Abstract

**Background:** Immediate hypersensitivity reactions to beta-lactams are IgE-mediated and constitute the most common adverse reactions to antibiotics mediated by a specific immunologic mechanism.

**Objective:** We investigated the association between four functional polymorphisms of IL13 (R130Q variant) and IL4RA (I50V, S478P and Q551R variants) genes and susceptibility to immediate allergic reactions to beta-lactams in the Algerian population.

**Methods:** We determined these gene variants in 199 patients and 99 healthy controls from Algeria. In a case-control study using the TaqMan method, we genotyped four single nucleotide polymorphisms (SNPs) including Arg130Gln in IL13, and Ile50Val, Ser478Pro as well as Gln551Arg in IL4RA.

**Results:** IL4RA I50V variant was more significantly connected with the risk of beta-lactam allergy ($P = 0.0144$) and the total serum IgE level in patients ($P = 0.0136$). A significant correlation was observed between IL13 R130Q and beta-lactam allergy ($P = 0.0384$). Also, a significant gene-gene interaction was detected between the predominant allele of the IL13 R130Q polymorphism and the three polymorphisms of IL4RA ($P < 0.0001$, $P = 0.0163$, and 0.0301, respectively). Haplotype analysis of IL4RA revealed that GTA haplotype had a significant correlation in patients with beta-lactam allergy ($P = 0.0123$).

**Conclusions:** Our results indicate that IL4RA (I50V) and IL13 R130Q are associated with beta-lactam allergy. The combination of IL13 and IL4RA variants markedly increases an individual’s susceptibility to beta-lactam allergy in the Algerian population.

**Key words:** Allergy, Beta-lactam, IgE, Interleukin-13, Interleukin-4 receptor, Polymorphism.

**Introduction**

Allergic reactions to beta-lactams are the most common cause of drug reactions mediated by specific immunological mechanisms, where immunoglobulin E (IgE) and T-cells play a role in the onset of allergic reactions. Hypersensitivity reactions are classified as either immune-mediated reactions or non-immune mediated reactions. Immediate hypersensitivity reactions are usually induced by an IgE-mediated mechanism and occur within the first hour following the last drug administration. These reactions typically appear as urticaria, angioedema, rhinitis, bronchospasm, or anaphylaxis. However, the mechanism by which allergic reactions are induced by beta-lactam antibiotics remains unclear.

IgE-mediated reactions also called immediate hypersensitivity reactions (Type-I hypersensitivity reactions) are classified as humoral mediated reactions. When exposed for the first time to an immunogenic drug, T-cells specifically T-helper-2
(Th2) cells, initiate an allergic reaction by releasing interleukin-4 and interleukin-13 (IL4, IL13), which activate and induce proliferation of B-cells. Then, activated B-lymphocytes produce antigen-specific Ig-E. There is a cross-link between multivalent antigen and basophils or mast cells by Ig-E specific for that antigen which leads to the degranulation of basophils and mast cells and release of inflammatory mediators. Interleukins secreted by Th2 cells, predominantly IL4 and IL13, are critical cytokines in the pathogenesis of allergic disorders. These interleukins share many biological and biochemical characteristics. Both IL4 and IL13 use the IL4 receptor α chain (IL4RA) as a component of their receptors and transmit their signals through IL4RA. Several studies reported in Europe, United States of America (USA), and China have also shown that immediate-type allergic reactions to beta-lactams are influenced by three genes that affect IgE production, IL13, IL4, and IL4 receptor α (IL4RA). In the present study, we thus aimed to evaluate the correlation between IgE-mediated reactions to beta-lactams and polymorphisms of IL13 (R130Q) and IL4RA (I50V, S478P, and Q551R variants) in the Algerian population.

Methods

Patients’ samples

Samples were taken from Allergy Unit at the Faculty of Medicine of Batna University in Algeria. The study was performed in 199 Algerian patients with immediate-type reaction to beta-lactams (penicillin or cephalosporins) occurring within 1 hour after drug administration, with positive skin tests and/or serum-specific IgE assays. The 99 healthy controls have no family relationship with cases. Informed consent was obtained from all subjects and the study was conducted according to the declaration of Helsinki Principles, and the ethics committee of Centre Hospitalo-Universitaire de Batna (CHUB, Algérie) approved the study.

IgE levels measurements and TaqMan method

Five mL of blood was taken from each participant under complete aseptic conditions and divided into two portions; 1.5 mL of whole blood was collected in sterile EDTA-containing tubes for DNA extraction, and the rest was left for 30 to 60 minutes for spontaneous clotting at room temperature and then centrifuged at 3000 rpm for 10 minutes. Serum samples were separated into another set of tubes and kept frozen at -20°C for determination of total IgE. Total serum IgE levels were measured by sandwich enzyme-linked immunosorbent assay ELISA (Innovative research Inc, Novi, Michigan, USA) following the manufacturer’s protocol. “Non enzymatic salting out” method was used to isolate genomic DNA from peripheral blood. All the polymorphisms were genotyped by allelic discrimination polymerase chain reaction assays (5’ nuclease assay) using predesigned TaqMan SNP Genotyping Assays (Applied Biosystems, USA). Both PCR primers and MGB TaqMan probes are shown in Table 1. Primers and probes annealing temperatures for all allele-discriminating assays were optimized using a standard PCR setup on a Bio-Rad CFX connect real-time PCR instrument (Bio-Rad Laboratories, Hercules, CA, USA). The program consisted of 3 minutes of polymerase activation at 98°C, followed by 40 cycles of collective annealing and elongation steps at 52-64°C (temperature gradient) for 30 seconds, and denaturation at 98°C for 15 seconds. For the optimization of the primer concentration, a titration series of each pair was prepared from 200 to 600 nM, with 300 nM of each of the two probes added, and using a heterozygotic sample as template DNA. Optimal annealing temperature, concentrations of primers and probes were selected based on the efficiency of the real-time PCR amplification. The main advantages of the direct approach for genotyping are less hands-on time during setup, and that the PCR is performed in a closed system, hereby minimizing the risk of contamination.

Reactions were performed in a 12 μL volume, consisting of six μL Bio-Rad SsoAdvanced Universal Probes Supermix, 500 nM of unlabeled PCR primers, 300 nM of TaqMan MGB probes, and 10 ng of template DNA. Thermal cycling was initiated with a denaturation step of 3 min at 98°C, followed by 40 cycles of 15 s at 98°C and 30 s at 60°C. After PCR were completed, allelic discrimination was analyzed using the Bio-Rad CFX Manager Software (Version 3.1, Bio-Rad). Genotype assignment was determined by plotting the endpoint relative fluorescent units (RFU) for one fluorophore (allele one on the

x-axis) against the RFU for the other fluorophore (allele two on the y-axis) on the allelic discrimination plot. All samples were set up in triplicate. PCR reactions were performed in a dedicated PCR area with dedicated PCR pipettes and reagents. For quality control purposes, each real time-PCR included negative as well as positive controls for all the genotypes. For validation, about 10% of the samples were re-genotyped. The results were reproducible with no discrepancies in genotyping.

**Statistical analysis:**

We used SNPstats software to test Hardy-Weinberg (HW) equilibrium of alleles frequencies. This software was also used to estimate haplotype frequencies in cases and controls. The chi-square test was used to test for significant association between beta-lactam allergies and alleles or genotypes. Odds ratio (OR), used as a measure of association strength, and the corresponding 95% confidence interval (CI) was calculated. Kruskal-Wallis test was used to assess whether the distribution of a categorical variable is the same between genotype groups. A P-value of less than 0.05 was considered significant. Statistical analyses were performed using GraphPad Prism version 7 (GraphPad Software, San Diego, CA).

**Results**

In the present case-control study, we explored the association between the IL13, IL4RA polymorphisms and beta-lactam allergy in a sample of Algerian population. The association between the immediate allergic reaction to beta-lactams and polymorphisms of IL13 (R130Q), IL4RA (I50V, S478P and Q551R) was evaluated in 199 patient and 99 healthy controls from Algeria. There were no significant differences in the distribution of age (P = 0.1023) and sex (P = 0.5554) between the cases and controls (Table 2). Patients with immediate allergic reactions had a significantly higher concentration of total serum IgE than controls (Table 2). All genotyped distributions of control subjects were consistent with those expected from the Hardy-Weinberg equilibrium (P > 0.05). Besides, the minor allele frequency (MAF) of all the four SNPs was consistent with that reported in the HapMap database (Table 3). No linkage disequilibrium was found between IL13 and IL4RA polymorphisms.

*MAF from the HapMap database

Genotype distributions and allele frequencies of all analyzed polymorphisms for the patients and control group are shown in Table 2. The frequency of the predominant alleles of IL4RA I50V and IL13 R130Q was significantly higher in patients than in controls, whereas no difference was observed for the IL4RA S478P and IL4RA Q551R (Table 2). We observed a significant association between IL13 R130Q and total serum level of IgE in patients as well as controls (P = 0.0002). The association of IL4RA I50V and S478P with total IgE was more significant when restricting the analysis to patients (Table 4).

Because of the biological relationship of IL4RA and IL13, an analysis was performed to determine if individuals with the risk genotypes for both genes were at higher risk of developing beta-lactam allergy. The data are summarized in Figure 1 and showed that IL13 130RR combined with any of the predominant homozygous genotypes of IL4RA was a risk factor in allergy to beta-lactams. A similar analysis was performed examining total serum IgE levels. Our results showed IL13/IL4RA variant combination: $P = 0.0220$, $0.0002$, $0.0020$, respectively and each variant $P = 0.0002$, $0.2224$, $0.6978$, $0.1237$, respectively. A linkage disequilibrium (LD) analysis was performed to study the relationships between the three SNPs of IL4RA and beta-lactam allergy. The LD showed that rs1805010 and rs1805015 had linkage disequilibrium with D’ of 0.5195, rs1805015 and rs1801275 had a score of D’ = 0.7977. However, rs1805010 and rs1801275 did not show linkage disequilibrium. Three haplotypes were found in the three SNPs of IL4RA gene: ATA, GTA, and GCG (Table 5). These haplotypes were observed in the case and control groups ($P < 0.0001$, $P = 0.0123$, and 0.3099, respectively). The haplotype GTA is correlated with beta-lactam allergy in Algerian population. Indeed, the haplotype GTA was significantly more frequent in patients with immediate allergic reactions to beta-lactams than in control subjects ($P = 0.0123$). Interestingly, the haplotype ATA was significantly more frequent in controls subjects than in patients ($P < 0.0001$).

NR: not reported
Discussion

Several studies suggested that allergic reaction to beta-lactams are influenced by genes involved in IgE production, including IL13 and IL4 pathways.\textsuperscript{6-11,17,18} Besides, recent population studies have reported an association between IL13 and IL4RA with atopy and asthma.\textsuperscript{19-21} In this study, we found for the first time in the Algerian population, an association of rs1805010 polymorphism in IL4RA gene and rs20541 in IL13 with an allergic reaction to beta-lactams.

In Algerian patients with allergic reaction to beta-lactams, we observed a higher concentration of total serum IgE than non-allergic patients suggesting the involvement of a genetic mechanism related to IgE class switching. Supporting our data, a relationship was found among IL4RA 150V and IL13 R130Q polymorphisms, the risk of immediate reaction to beta-lactams, and total serum IgE level.\textsuperscript{1} However, Apter et al. reported that the IL4RA 150V polymorphism had no relationship with penicillin allergy based on a series of 23 self-reported penicillin -allergic patients from USA.\textsuperscript{10} One possible explanation for this discrepancy is the difference in the genotype frequency of ILR4A 150V between different populations. This explanation is supported by the research of Gueant et al. who showed that the IL4RA 150V of the AA genotype was more significantly associated with the risk of penicillin allergy than with the risk of cephalosporin allergy.\textsuperscript{17} This study also demonstrated that a difference in the AA genotype frequency of IL4RA 150V existed between two Europeans populations.\textsuperscript{17}

The IL4RA gene is located on chromosome 16p11–16p12. It is a subunit that plays a key role in allergic disease by promoting the IgE production.\textsuperscript{22} In our study, the 150V and S478R were correlated with IgE production in patients, whereas the Q551R was not associated with the IgE level (Table 4). However, Cornejo-Garcia et al. found that total IgE was affected by Q551R polymorphism as well as IL13 130RQ/QQ and IL4RA 551QQ epistatic genotype in Spanish Caucasians.\textsuperscript{12} In our series, the two symmetrical combinations (IL13 130RR and IL4RA 50II, IL13 130RR and IL4RA 551QQ) are significantly correlated with total IgE level, but less than the effect of IL13 R130Q alone (P = 0.0002), confirming the critical role of IL13 in the initiation of IgE production.\textsuperscript{23-26} These gene-gene interactions were consistent with the complementary role of both molecules in IgE switching.\textsuperscript{8} Another interesting finding of our study, is the combination of the predominant allele of IL13 R130Q polymorphism with any of the predominant homozygous genotypes of the three polymorphisms of IL4RA (150V, S478P, and Q551R) was more significantly associated with the risk of beta-lactam allergy (P < 0.0001, p = 0.0163, 0.0301, respectively) than any polymorphism considered alone (P = 0.0093, 0.0031, 0.2059, 0.6000, respectively). Also, the symmetrical combinations (IL13 130RQ/QQ and IL4RA 50II), and (IL13 130RR and IL4RA 50IV/VV) were significantly associated with the risk of beta-lactam allergy, while the other combinations were not significant (Figure 1). Table 6 shows genetic association studies that reported genetic predictors in association with beta-lactam allergy compared with our study. These studies suggested that pro-inflammatory cytokine genes such as IL4R, IL4, IL13 are involved in IgE mediated beta-lactam reactions.

Computer modelling of the rs20541 variant has shown that this substitution affects the signal strength between interleukin 13 and its receptor.\textsuperscript{27} This polymorphism encodes an amino acid residue, which is located within the D helix, close to the C-terminal region of IL13.\textsuperscript{28} IL13 is a ligand of the IL4RA subunit; it is thus possible that the R130Q polymorphism influences the interaction between D helix and the IL4RA subunit. The underlying molecular mechanisms of this association need to be clarified because the computer modelling of the IL13/IL4RA interaction suggests that the arginine of the 130RR variant repulses the histidine 131 of IL4RA.\textsuperscript{22} The S478P and Q551R variants of IL4RA may intensify the downstream signalling, because of their position close to a STAT6-recruiting domain.\textsuperscript{28} Therefore, additional genes related to the signalling pathways of IL4RA, such as IL4, STAT6, and JAK1, could also account for an additional risk of IgE mediated allergy to beta-lactams, as previously suggested in probands with asthma susceptibility.\textsuperscript{22}

In the haplotype analysis of the IL4RA gene, the GTA haplotype frequency in patients with beta-lactam allergy was found to be significantly higher than the control group suggesting an interaction between the three polymorphisms regarding susceptibility to beta-lactam allergy. In other words, the results indicate that GTA haplotype could be associated with the susceptibility to beta-lactam allergy in the Algerian population. The association of G50, T478 and A551 combination with beta-lactam allergy was higher than each allele alone, suggesting that haplotype analysis can provide more information than the single SNP alone. Moreover, it is interesting to observe that the haplotype ATA seems to have a protective effect against beta-lactam allergy, although the reason is unclear. Thus further studies should be undertaken to analyse the putative relevance of haplotypes of IL4RA Ile50Val, Ser478Pro and Glu551Arg polymorphisms in the development of beta-lactam allergy.

Conclusion

In summary, our study suggests that IL4RA 150V and IL13 R130Q polymorphisms are related to beta-lactam allergy. Our data demonstrate that IL13 is a more potent predictor of beta-lactam allergy than IL4RA. In the Algerian population, a significant association of IL3/IL4RA polymorphism combinations with beta-lactam allergy and IgE levels is observed. However, additional studies are needed to confirm these results in other populations. Also, our data suggest that the haplotype GTA from rs1805010, rs1805015, and rs1801275 of IL4RA may be related somehow to beta-lactam allergy. This relationship needs to be further studied using a larger sample.

Our results have a certain clinical implication. The identification of genetic risk factors may improve the diagnosis and understanding of the pathophysiology of beta-lactam allergy. Therefore, having a clear view of the genetic factors involved can lead us to develop better preventive methods and strategies as well as effecting better drug design and treatment strategies in the future.

Prevalence of allergic rhinitis comorbidity with asthma and asthma with allergic rhinitis in China: A meta-analysis

Yang Shen,1 Ji-Hong Zeng,1 Su-Ling Hong,1 Hou-Yong Kang1

Abstract

Background: Allergic rhinitis (AR) and asthma are the most common inflammatory diseases of the airways. The relationship between asthma and AR is widely and clinically recognised. The concept “one airway, one disease” has been gradually accepted. However, in China, we could not find any systematic review and meta-analysis on the prevalence of AR with asthma and asthma with AR.

Objective: The aim of this research was to carry out a meta-analysis on the results of all conducted studies to present valid information about the co-occurrence rate of AR with asthma and asthma with AR in China.

Methods: Pubmed/Medline, Science, Springer, Elsevier, Embase, Wanfang data, VIP, CBM, and CNKI were searched systemically and data were extracted from eligible studies by two independent reviewers. Meta-analysis, study quality assessment, and publication bias assessments were all done using Stata 12.1 software.

Results: The results of this meta-analysis showed that pooled prevalence estimates of AR with asthma ranged from 6.69% to 14.35%, asthma with AR from 26.67% to 54%. Furthermore, an overall prevalence of 10.17% (95% CI 9.08–11.27%) was ascertained for AR with asthma, and 38.97% (95% CI 34.42–43.53%) for asthma with AR.

Conclusions: The present meta-analysis comprehensively provided the first quantitative summary of the prevalence of AR with asthma and asthma with AR in China. Our study demonstrated that, in China, asthma and AR are often comorbid diseases and co-exist in the same patients. There is a close correlation between AR and asthma from an epidemiological standpoint.

Key words: allergic rhinitis, asthma, comorbidity, prevalence, China

Introduction

Allergic rhinitis (AR) and asthma are the most common inflammatory diseases of the airways. The prevalence of AR is 10–40% worldwide.1 Our previous epidemiological investigations showed that in Western China, the prevalence of self-reported AR was 32.3% (Chongqing), 34.3% (Chengdu), 37.9% (Urumqi), and 30.3% (Nanning).2 Globally, the prevalence of asthma has more than doubled over the past 20 years.3 The prevalence of asthma has been reported to vary in different countries: 10% in the United Kingdom, 4.8% in France, 4.8% in Germany, 4.7% in Italy, and 4.8% in Spain.4,5

The relationship between asthma and AR is widely and clinically recognised. Grossman first described the concept “one airway, one disease” in 1997, mainly from the pathophysiological roles of leukotriene inflammation in the upper and lower airways.6 Research showed that many patients with asthma, particularly those with allergic asthma, also have AR. The mucosa of the upper and lower airways is continuous, and the types of inflammation in AR and asthma are very similar, involving T helper type 2 cells, mast cells, and eosinophils. Both diseases have characteristic symptoms and are strongly...
Influenced by environmental factors. Previous studies demonstrated that among patients with asthma and concomitant AR, those who received treatment for AR had a significantly lower risk of subsequent asthma-related events (emergency care visits/hospitalisations) than those who did not receive treatment. Ohta et al. found that in Japan, AR is a common comorbidity (67.3%) in asthma and that it impairs asthma control.

The data about the prevalence of allergic rhinitis, asthma among the Chinese population may affect the decision of policy makers, insurance organisations, and health authorities. Although, there are a few studies about the prevalence of AR and asthma in China, we could not find any systematic review and meta-analysis on the prevalence of asthma and AR among the Chinese population, especially the prevalence of AR with asthma and asthma with AR. Thus, the aim of this research was to carry out a meta-analysis on the results of all conducted studies to present valid information about the prevalence of AR with asthma. In addition, we aimed to investigate the co-occurrence rate of AR with asthma and asthma with AR in China.

Materials and Methods

Preferred reporting items for systematic reviews and meta-analyses (PRISMA) guidelines were followed while performing this meta-analysis and associated systematic review.9

Literature search

Sensitive, systematic searches were separately conducted by two trained researchers to find studies on allergic rhinitis and asthma. Several electronic databases including Pubmed/ Medline, Science, Springer, Elsevier, Embase, Wanfang data, VIP, CBM, and CNKI were searched for relevant articles. The major medical subject headings (MeSH) and keywords used in different logical combinations and phrases included “allergic rhinitis”, “asthma”, “epidemiology/prevalence/morbidity/incidence/attack rate”, and “comorbidity”. The search encompassed original research papers published from 2006 to 2016.

Inclusion and exclusion criteria

We included population-based studies that reported the prevalence of allergic rhinitis and asthma among Chinese populations. The inclusion criteria were: (1) studies reporting the prevalence of allergic rhinitis, asthma, allergic rhinitis with asthma, and/or asthma with allergic rhinitis; (2) studies reporting the exact diagnostic criteria; (3) cross-sectional studies; and (4) study reports with data in forms that were able to be utilised in the meta-analysis. The exclusion criteria were: (1) repeated publications; (2) reviews; (3) studies providing insufficient data; and (4) a methodological quality score less than 5.

Data extraction

Initially, two researchers independently reviewed all the titles and abstracts that were selected using the keywords. In the second phase, full texts of the articles, which were selected in the first phase, were reviewed; finally, the researchers selected the articles whose contents were suitable for data extraction. Disagreements between the two reviewers about selecting articles were resolved by a third reviewer via discussion and consensus. Extracted information included name of the first author, year of publication, type of study (local study or survey), total sample size, number of patients, point prevalence, and 95% confidence interval (CI) of point prevalence.

Study quality assessment

The global burden of disease quality assessment checklist was used to assess the quality of the studies. Total study quality score was achieved by summing the sampling method (1–4 score), the sample size (0–3), and the response rate (0–6).10

Statistical analysis

The AR with asthma and asthma with AR prevalences were calculated using the random effects model with 95% CI. To evaluate heterogeneity, we estimated the proportion of between-study inconsistency using the I² statistic, with values of 25%, 50%, and 75% considered low, moderate, and high, respectively. If the heterogeneity was significant and I² > 50%, the random-effect model was adopted; otherwise, the fixed-effect model was used. All statistical tests were performed using Stata software version 12.1 (Stata Corporation, College Station, TX, USA).

Results

Literature search

Following the development of our search strategy, a total of 783 relevant articles were selected from primary research in electronic databases. After deleting duplicate articles and reviews, 325 potential articles were obtained. Then, 278 articles were excluded due to irrelevance to the study subject after evaluation of titles and abstracts, so 47 articles were included into the study for reviewing full-text. Finally, 26 articles were excluded after reviewing full-texts due to inappropriate study design and/or outcome. Thus, 21 studies that met inclusion criteria were included in the meta-analysis and summarised in Figure 1 and Table. 1.

Figure 2. A funnel plot of the overall meta-analysis of metabolic and endocrine comorbidities reflecting publication bias. (a. AR with asthma; b. asthma with AR)
Study characteristics
The selected studies were published from 2006 to 2016 and all the included articles were carried out as cross-sectional surveys, including 133813 participants and 10042 AR patients and 3182 asthma patients in the articles that comprised this meta-analysis. Publication bias assessment was made by visual examination of the funnel plot symmetry. (Figure 2)

Estimated prevalence of AR comorbid with asthma
Eleven studies about AR with asthma in China were selected in this research. Based on the results of random effect method, the overall prevalence of AR comorbid with asthma in China was 10.17% (95% CI 9.08–11.27%). In total, 10042 AR patients with an average of 913 AR patients per study were evaluated. The highest prevalence was reported by Chen Xing et al. in 2015 (14.35%) and the lowest by Yang Li et al. in 2015 (6.79%). (Figure 3, Table 1)

Estimated prevalence of asthma comorbid with AR
Ten studies about asthma with AR in China were selected. The overall prevalence of asthma comorbid with AR in China was 38.97% (95% CI 34.42–43.53%). In total, 3182 asthma patients with an average of 32 asthma patients per study were evaluated. The highest prevalence was reported by Li Seng et al. in 2013 (54%) and the lowest by Feng Qiuyue et al. in 2015 (26.67%). (Figure 4, Table 1)

Discussion

Allergic rhinitis and asthma are both caused by an inappropriate immunological response to antigens compared to the response elicited in most individuals. Our study presented a comprehensive report about the prevalence of AR with asthma and asthma with AR. The results of this meta-analysis showed that pooled prevalence estimates of AR with asthma ranged from 6.69% to 14.35% and asthma with AR from 26.67% to 54%. Furthermore, an overall prevalence of 10.17% (95% CI 9.08–11.27%) was determined for AR with asthma, and 38.97% (95% CI 34.42–43.53%) for asthma with AR. This study presented a comprehensive report that is the first quantitative summary of the prevalence of AR with asthma and asthma with AR in China. The results of this meta-analysis demonstrated a close correlation between AR and asthma from an epidemiological perspective.

AR and asthma, rather than being considered two distinct diseases, can be unified by the concept of a “united airway,” where allergic symptoms of the upper and lower airways can be thought of as manifestations of a common atopic entity. Both diseases, which are IgE mediated, can be triggered by similar allergens, including mold, animal dander, and house-dust mites. Epidemiological studies have shown that the majority of patients with asthma have concomitant rhinitis and the presence of rhinitis is an increased risk factor for the development of asthma. The prevalence of asthma is < 2% in subjects without rhinitis while it varies from 10% to 40% in patients with rhinitis. Meanwhile, AR occurs in > 75% of patients with asthma, whereas asthma affects up to 40% of patients with AR. In a 10-year longitudinal study of children with AR, asthma was eventually found in 19% of the cases, and in 25% of the sample size asthma and AR developed simultaneously. In a 23-year follow-up study of almost 2000 college students, patients with AR, when compared with controls without AR, were about three times more likely to develop asthma. Pefura-Yone et al. reported that the prevalence of rhinitis was 27.3% among subjects with current wheezing and 25.4% of participants with asthma had rhinitis in Cameroon. Furthermore, in Japan, a nationwide survey of asthmatic patients revealed that 67.3% of asthmatic patients had AR. In addition to the epidemiological evidence, several clinical reports point to a common pathophysiological relationship between AR and asthma. Our meta-analysis demonstrated the prevalence of AR with asthma and asthma with AR in China. The results supported that asthma and AR are often comorbid diseases and co-exist in the same patients. Meanwhile, our data showed the prevalence of asthmatic patients with AR in China to be lower than in Japan. On the one hand, we think the difference may partly be ascribed to regional disparity. On the other hand, environmental factors and different allergens may also play roles.

Based on the results of previous research and our meta-analysis, we know that there is a close correlation between AR and asthma; AR is highly comorbid with asthma and is a risk factor for asthma. These studies indicate that establishing the overall concept of upper and lower airway is particularly important for AR and asthma treatment. Thus, on the one hand, we should pay attention to the evaluation of the lower airway of AR patients, using pulmonary function tests, bronchial provocations, chest radiograph, and so on. On the other hand, in the process of asthma treatment, we should note to control the symptoms of AR.

Nevertheless, there are some several limitations to the present meta-analysis. First, the number of studies included was comparatively small. Second, the lack of detailed descriptions of AR and asthma features (such as atopic status, age of onset, and disease severity) constrained further subgroup analyses. Third, our study only included the studies from the last 10 years. As we all know, the environment has changed greatly during this time span. Thus, the changes in environmental risk factors for AR may have partially biased the results of this meta-analysis. Meanwhile, in this research, only published studies were reviewed; as a result, unpublished studies and gray literature were not included in our analyses because they were not accessible. Such sets of data could have greatly impacted our results.

In conclusion, the present meta-analysis comprehensively provided the first quantitative summary of the prevalence of AR with asthma and asthma with AR in China. The results of this study showed that the overall prevalence of AR with asthma and asthma with AR was 10.17% and 38.97%, respectively. Our study demonstrated that asthma and AR are often comorbid diseases and co-exist in the same patients. There is a close correlation between AR and asthma from an epidemiological perspective. These results can fill the knowledge gaps about the prevalence of respiratory diseases in China, and it can help policy makers, specialists, insurance companies, and all stockholders to make plans and evaluate the medical services required to reduce the prevalence of respiratory diseases.

Prevalence of AR and asthma in China

Prevalence and severity of asthma, rhinoconjunctivitis and eczema in children from the Bangkok area: The Global Asthma Network (GAN) Phase I

Sasawan Chinratanapisit,1 Narissara Suratannon,2 Punchama Pacharn,3 Paskorn Sritipsukho,4,5 Pakit Vichyanond3

Abstract

Background: As noted in the reports of ISAAC phase I and III, allergic diseases are very common in Thailand, especially among younger children.

Objective: The objectives of this project are to study the prevalence and severity of the most common allergic diseases, i.e. asthma, rhinoconjunctivitis and eczema among children living in Bangkok.

Methods: A cross-sectional multi-centers survey using GAN Core questionnaires on asthma, rhinoconjunctivitis and eczema symptoms were completed by parents of children aged 6–7 years and children aged 13–14 years.

Results: The total of 6,291 questionnaires were eligible for the analysis. The cumulative vs. 12-month period prevalence of the three conditions for all children were: 24.4% vs. 13.5% for wheezing, 51.1% vs. 43.6% for rhinitis and 15.8% vs. 14.2% for eczema, respectively. The period prevalence of wheezing for younger children (14.6%) was higher than for older children (12.5%). Prevalences of severe wheeze and exercise wheeze were more common among older children (2.9% and 14.8%). The 12-month prevalences of rhinitis (43.6%) and rhinoconjunctivitis (16.3%) were higher in both age groups. Eczema, as the same to the other conditions, occurred more frequently in both groups (period prevalence of 14.3% and 14.0%) comparing to ISAAC phase III.

Conclusion: Allergic conditions are very common diseases among children residing in Bangkok. There is an urgent need for an in-depth study to define epidemiological factors responsible for this increase.

Key words Asthma, rhinoconjunctivitis, eczema, ISAAC, GAN

Introduction

Allergic diseases are among the most common chronic diseases in children and adolescents leading to a substantial health and socioeconomic burden. The International Study of Asthma and Allergy in Childhood (ISAAC) phase I and III surveys reported an overall increase in the prevalence of eczema and allergic rhinoconjunctivitis worldwide. However, no changes in the prevalence of asthma among 13-14-year-old children over a mean period of 7 years was observed.1-3 The ISAAC phase I study in Thailand was conducted in 1995-1999 in 3 cities namely; Bangkok,4 Chiang Mai5 and Khon Kaen.6 In Bangkok, the prevalences of three conditions were: asthma 18.3%, rhinitis 44.2% and eczema 15.4%. The ISAAC phase III studying in Bangkok shown that there is a trend of increasing prevalence of all atopic diseases among children.7 The Global Asthma Network (GAN), established in 2012, was formed by scientists from the International Study of Asthma and Allergies in Childhood (ISAAC) 1991–2012 (phases
Prevalence of Asthma, AR and AD in Bangkok

I, II, III and IIII and from the International Union Against Tuberculosis and Lung Disease (The Union) following production of the first Global Asthma Report (GAR) launched in New York (NY, USA) in 2011 at the time of the United Nations high-level meeting on non-communicable diseases. GAN phase I, builds on the ISAAC findings by collecting further information on asthma, rhinitis and eczema, prevalence, severity, diagnoses, asthma emergency room visits, hospital admissions, management and the use of asthma essential medicines.

The objectives of our project are to study the prevalence and severity of the most common allergic diseases. i.e. asthma, rhinoconjunctivitis and eczema in children living in Bangkok. We, herein, report the results of our GAN phase I study in 6,291 children from the two age groups living in the Bangkok area.

Methods

Study Design

This study is a cross-sectional, multi-center, study design.

Participants

Seven primary schools and six secondary schools in Bangkok were randomly mapped, stratified and had chosen to represent the population of the entire Bangkok Metropolitan area. In addition, equal numbers of governmental and private schools were selected to avoid an over representation of any predominant socioeconomic classes. Subjects were selected in the same manner as ISAAC phase III. The same age groups were used: 13-14 years old adolescents (self-completed questionnaires) and 6-7 years old children (parental completed questionnaires) and GAN phase I adds their parents as an adult group. Students of both age groups were selected either by grade/level/year or by age group. The questionnaires were sent out to 6,824 children (3,544 for 6-7 years and 3,280 for 13-14 years). Although participation rates for both age groups from these schools were exceptionally high (92.18%), many questionnaires were incompletely answered and were therefore excluded from the analysis. This left a grand total of 6,291 children (3,074 for 6-7 years and 3,217 for 13-14 years) for the inclusion of the analysis. The study was approved by the Medical Research Ethics Committee of the Royal Thai Army at the Medical Sciences Division, Naresuan University (054/2560) and the Human Research Ethics Committee of the Royal Thai Army (MTU-EC-ES-4-013/60). Inform consents/assents were obtained by the parents.

GAN Core Questionnaires

GAN Standardized Written Core Questionnaires developed from ISAAC Questionnaires for use in phases I and III, were used in GAN. Demographic questionnaires includes the participant’s name, age, date of birth, school (for the adolescents and children), sex and date of interview. Questionnaires were coded by using a unique number for each center, school and participant to ensure confidentiality and to link the questionnaires between the adults, adolescents and children. The written core questionnaires, that was used in ISAAC, have had a question about doctor-diagnosis about asthma, rhinitis and eczema. The core questions were both sensitive and specific, had good content, constructive and concurrent and predictive validity. As in ISAAC, a video of asthma questionnaires was an optional tool: the international version that is being used in ISAAC. This 6-minute non-verbal video showed the clinical signs of asthma symptoms and was developed by the Wellington Asthma Research Group, in order to avoid the problems of translation and understanding of terms of “wheeze” or “whistling” and their uses in culturally heterogeneous population. The video has the advantage of obtaining data from many students quickly and efficiently. The questionnaires were translated into Thai and back translated by a three linguistic proficient individuals and were reviewed and approved by the investigators.

Sample Size

As in ISAAC, a sample size of 3,000 participants per age group (and therefore potentially 6,000 adults of each group) was used. The sample size provided greater than 99% ability (at the 1% level of significance) to detect differences in the prevalence of wheezing of 30% in one center and 25% in another center. As sampling was done by schools, and the information gained from the school pupils and adults, is likely to be a cluster effect. Like ISAAC, the analysis incorporated adjustments in cluster sampling using the design effect, which is important for large studies where clusters of different sizes may be used in different regions. High participation is sought for GAN phase I: at least 80% for 13-14 years old and 70% for 6-7 years old and 70% for adults/parents.

Data Collection and Analysis

Data were collected from July 2017 up to February 2018. Information on the questionnaires was entered in the GAN Epi-Info data entry packaged by GAN Global Center in Auckland, New Zealand (info@globalasthmanetwork.org). Such data were analyzed by using STATA version 14 and expressed in the prevalence of three diseases in both the younger and older groups, separately.

Results

Positive response to wheezing modules for younger and older age groups as well as for all children surveyed are tabulated in Table 1. All participants are Thai. The prevalence of ever-wheeze in the younger age group was slightly higher than in the older age group (26.0% vs. 22.9%, p = 0.004). This was also true for percentage of current wheeze or wheeze in the past 12 months (14.6% vs. 12.5%, p = 0.016) and for attacks within the past 12 months (14.4% vs. 12.6%, p = 0.029). Percentages for severe wheeze (1.9% vs. 2.9%, p = 0.019) and exercise wheeze (3.0% vs. 14.8%, p < 0.001) were much higher among older children. Percentages of night awakening were slightly higher among the younger age group (6.7% vs. 4.2%, p < 0.001). Percentages of night cough were noticeably high in both groups (24.2% and 29.9%, p < 0.001). The prevalence for diagnosed asthma (asthma-ever, 6.1% and 8.8%, p < 0.001) were much lower than wheezing-ever for both groups (26.0% and 22.9%). As for male: female ratio, there was no predominance for males over females other than responses for question of ‘asthma ever’ (1:3.6).

Current rhinoconjunctivitis or Current AR: Current nose symptom and current eye symptom
Severe rhinoconjunctivitis: Current rhinoconjunctivitis and answer A LOT to question “In the past 12 months, how much did this nose problem interfere with your (child) daily activities?”
P Value for Chi square test of positive response symptom between age groups

The self-reported video questionnaires completing by the 13-14-year-old group revealed a cumulative vs. current prevalence of: wheezing at rest (11.9% vs. 8.9%), exercise wheeze (13.5% vs. 9.0%), night wheeze (6.6% vs. 5.6%), night cough (23.4% vs. 17.9%) and severe wheeze (8.1% vs. 5.8%) (Table 2). Percentages for night wheeze (5.6%) was slightly higher than that derived from the written questionnaires (4.2%). The video responses to exercise question (9.0%) was lower than that from the written ones (14.8%). The prevalence of severe wheeze from video responses was 5.8%, which is twice of the written questionnaire (2.9%).

In Table 3, prevalences of rhinitis and other associated symptoms are shown. An exceptionally high number of children from both age groups (47.3% and 54.9%) reported nasal
The cumulative prevalence of wheezing based on the video questionnaires from this study (11.9%) is closed to the prevalence of the ISAAC study phase III from Bangkok (11.5%). This is much higher than the Asia-Pacific prevalence (5.5%) and, also the global prevalence (8.7%) of the ISAAC study phase III. The prevalence of severe asthma (written questionnaires) in the 13-14 years age group is 2.9%. This is lower than the prevalence of severe asthma from the ISAAC study phase III: globally (6.9%) ranging from 3.8% in Asia-Pacific, Northern and Eastern Europe to 11.3% in North America (compared to Bangkok 4.0%).

Positive responses to questions in the eczema module are shown in Table 4. The percentage of younger children reported ‘rashes within the past 12 months’ was 14.3% and up to 11.7% indicated rashes localized in areas typical diagnosis of atopic dermatitis. Slightly lower numbers were reported in older children (14.0% and 10.0%). Many children with a rash indication had mostly cleared within the past twelve months (9.1% and 10.0%), and the term ‘hay fever’ does not exist in the Thai language, 27.4% indicated that they suffered from ‘allergy to the air’, a common term denoting hay fever in Thai.

In our study, there were strong associations with other allergic diseases: in asthma patients: 32.5% had AR and 21.8% had eczema, AR patients: 27.1% had asthma and 24.6% had eczema, eczema patients: 37.1% had asthma and 27.4% had AR.

Severe eczema: Current eczema associated with sleep disturbance 1 or more nights per week
P Value for Chi square test of positive response symptom between age groups

The new GAN phase I survey, however, portrayed a differing epidemiological outlook than from what has been felt among practitioner caring for asthmatic patients. These preliminary data have shown that prevalence of asthma in younger and older children is still over 10% of the population surveyed. Moreover, the prevalence for those with severe wheeze is roughly 2%. The Chest and Allergy Societies in Thailand have regularly updated asthma guidelines for adults and children. Besides, social media has made it easier for parents/patients to find appropriate professional care. An increase in the availability of asthma controllers throughout the country may help lessen the severe asthma attacks presented to emergency rooms and requiring hospital admissions in this country. Among these drugs, inhaled steroids are very popular. Since generic versions of these controllers are cheaper than original version, they were included in Essential Drug List subsidized by the Government for those eligible for medical supports (governmental employees, those under the social security program and universal health coverage). Effective advocacy by non-governmental organizations, smoking in homes and public places is now rare event. Thailand has enforced stricter regulations to reduce outdoor air pollution, such as cleaner air emissions and vehicle fuels.
Ecological economic analyses also revealed that although the high-income centers tended to have a higher prevalence of current wheeze, a reverse trend was found in the prevalence of symptoms of severe asthma among current wheezers. There may be several reasons underlying this observation. First, asthma care is likely to be poorer in these developing countries, although a recent epidemiological survey showed that suboptimal asthma management was a global phenomenon. Secondly, there may be less awareness of wheeze being a symptom of asthma, even in those with frequent wheezing, similar to the situation amongst ethnic minorities in developed countries. This notion is further supported by the finding that undiagnosed asthma among those current wheezers with severe asthma symptoms was most commonly seen in these lower income countries. Children with undiagnosed frequent symptoms are also more likely to receive inadequate care for their asthma and may fall into a vicious downward spiral of asthma control. Thirdly, differences in the levels of environmental exposure, including air pollutants and infective agents, may also contribute to the greater severity observed in these countries.

GAN phase I has provided the most comprehensive estimate of the worldwide symptom prevalence of asthma to date. This global map of asthma is invaluable not only for public health planning, but also for generating hypotheses in explaining the etiological factors for this common disorder.

In our study, the prevalence of current AR or current rhinoconjunctivitis in the 6–7 year and 13–14-year age groups are 15.0%, 17.5% respectively. As the ISAAC phase III, the prevalence of current AR of Thai children from the Bangkok area were 13.4% and 23.9% respectively.7 It is slightly higher than the mean of global prevalence (9.1%, 16%), and the Asia-Pacific prevalence (5.8% and 14.5%).

In our study, the prevalence of current eczema symptoms in the 6–7 years and 13–14 years age groups are 14.3%, 14.0% respectively. These values are slightly higher than those from the ISAAC study phase III in Bangkok (13.3% and 10.4%)7. However, our GAN results on eczema is much higher than the ISAAC study phase III study elsewhere: the mean global prevalence (7.9%, 7.3%) and the Asia-Pacific prevalence (4.7% and 5.3%).

For developing countries, Thailand has been noted to has an increased in the number of patients with food allergy and atopic dermatitis. The reason for this worrisome and unusual increase is uncertain at this point. Similarly, results of GAN phase I survey substantiate the increasing numbers of children in both age groups. If a phenomenon of allergic march operates in this part of the world, one should witness an increase in the number of asthmatic patients rather than a decrease in the next decade.

Strengths and Weaknesses of the Study

The major strengths of our study included a standardized written core questionnaires (GAN 2016) developed from ISAAC Questionnaires, well-established standardized protocol and high response rate. The establishment of GAN 2016 questionnaires allows an excellent opportunity for different countries to establish their own basic epidemiological data for allergic diseases that can be compared internationally. A video asthma questionnaire (6-min non-verbal video) shows clinical signs of asthma symptoms to avoid problems of translation and comprehension of terms such as "wheeze" or "whistling" and their use in culturally heterogeneous population. One limitation of our study is that symptoms of allergic rhinitis were self-reported in the questionnaire, therefore, we could not confirm with physical examination and laboratory investigations.

In conclusion, the result of GAN phase I in Bangkok showed a slightly increase of prevalence of eczema in both age groups, while prevalences of asthma and allergic rhinitis have become stabilized in both age groups. Most Thai children with asthma had coexisting rhinitis, and a portion of patients with rhinitis also had asthma. Allergic conditions are very common among children residing in Bangkok. There is an urgent need for an in-depth study to define epidemiological factors responsible for this increase.

Acknowledgements

The study was completed with significant contributions from the colleagues of Allergy centers, Bhumibol Adulyadej Hospital. The authors wish to thank: Prof. Orphan Phoachanukoon Asst. Prevalence and risk factors of allergic rhinitis in children in Bangkok area

Sasawan Chinratanapisit,1 Narissara Suratannon,2 Punchama Pacharn,3 Paskorn Sritipsukho,4,5 Pakit Vichyanond3

Abstract

Background: Allergic rhinitis (AR) is a disease with a high global disease burden and significant morbidity and expense. Risk factors are not well understood.

Objective: The objective of our project is to study the prevalence and risk factors of AR in children living in the Bangkok area.

Methods: A cross-sectional, multi-center survey using new GAN core questionnaires on current AR and risk factors was completed by 3,074 parents of children aged 6–7 years and by 3,217 children aged 13–14 years, directly.

Results: The prevalence of current AR in children aged 6–7 years and 13–14 years was 15.0% (95% confidence interval [CI]: 13.8–16.3%) and 17.5% (95% CI: 16.2–18.8%), respectively. The prevalence of severe AR in children aged 6–7 years and 13–14 years was 1.0% (95% CI: 0.6–1.3%) and 1.9% (95% CI: 1.4–2.4%), respectively. Co-morbidity with asthma and eczema was 27.1% and 24.6%, respectively. Significant factors associated with AR include parental history of asthma (p = 0.025), parental history of AR (p < 0.001), parental history of eczema (p < 0.001), lower respiratory tract infection in the first year of life (p < 0.001), breastfeeding (p = 0.019), current use of paracetamol (p < 0.001), exercise (p < 0.001), current cat exposure (p = 0.008), and truck traffic on the street of residence (< 0.001).

Conclusion: AR is a common disease among children residing in Bangkok. This study confirms that a family history of atopy (asthma, AR, and eczema), antibiotics given in the first year of life, current paracetamol use, exercise, current cat exposure, and truck traffic on the street of residence are important and significant risk factors for AR symptoms.

Key words: allergic rhinitis, atopy, asthma, ISAAC, GAN

Introduction

Allergic rhinitis (AR) is characterized by paroxysms of sneezing, rhinorrhea, and nasal obstruction, often accompanied by itching of the eyes, nose, and palate. Postnasal drip, cough, irritability, and fatigue are other common symptoms.1,2 AR is associated with significant morbidity and expense.3,4

The increase in the prevalence of AR began to attract attention from epidemiologists in the late 1980s. The International Study of Asthma and Allergies in Childhood (ISAAC) was initiated to establish the prevalence of allergic diseases in 257,800 school children aged 6–7 years and in 463,801 children aged 13–14 years using standardized and validated questionnaires.7 Phase I of ISAAC, which began to enroll patients in 1992, sought to establish prevalence rates in nearly 60 countries on every continent; phase II investigated variables contributing to AR (e.g., environmental exposures); and phase III provided follow-up data on the patients at least five years after entry into the study. In phase I, prevalence rates for AR collected across all centers ranged from 0.8% to 14.9% (median, 6.9%)
Prevalence and risk factors of allergic rhinitis in children in the Bangkok area

in the 6–7-year-olds and from 1.4% to 39.7% (median, 13.6%) in the 13–14-year-olds. The highest prevalence rates for AR were observed in parts of Western Europe, North America, and Australia, whereas the lowest rates were found in parts of Eastern Europe and South and Central Asia. The phase III analyses revealed that the prevalence rates had increased, with 12-month prevalence rates of 1.8% to 24.2% in children aged 6–7 years (median, 8.5%) and 1.0% to 45% (median, 14.6%) in children aged 13–14 years. These findings strongly indicate that the prevalence of AR has increased over a relatively short period of time, mostly in Westernized countries with a higher standard of living.

According to phase I of ISAAC in Bangkok (1995–1999), the prevalence of AR was 10.0% in the children aged 6–7 years and 15.4% in the children aged 13–14 years. In phase III of the study in Bangkok (2001), the prevalence of AR in children aged 6–7 years and 13–14 years was 13.4% and 23.9%, respectively. There was an increase in the prevalence of rhinitis in both age groups.

Phase III of ISAAC included new questions on risk factors that identified several environmental associations. Risk factors for AR include paracetamol, antibiotics, truck traffic, breastfeeding, farm animals, cats and dogs, air pollution, tobacco, body mass index (BMI), diet, cooking fuels, birth weight, migration, and siblings. Despite the considerable research efforts, the risk factors of AR remain poorly understood. A family history of atopic diseases seems to be a major risk factor, but various environmental factors and lifestyle are also considered important elements in the evolution of the disease.

The objective of our project is to study the prevalence and risk factors of AR in children living in Bangkok, Thailand.

Methods

Study Design

This study has a cross-sectional, multi-center design.

Participants

Seven primary schools and six secondary schools in Bangkok were randomly mapped, stratified, and chosen to represent the population of the entire Bangkok metropolitan area. Subjects were selected in the same manner as ISAAC phase III. The same age groups were recruited: 13–14-year-old children (self-completed questionnaires) and 6–7-year-old children (parent-completed questionnaires). Of 6,834 questionnaires sent to children, 6,291 were completed (95.05%). There were 3,074 (86.49%) questionnaires of children aged 6–7 years and 3,217 (98.08%) questionnaires of children aged 13–14 years available for analysis. The study was approved by the Human Research Ethics Committee of Thammasat University (054/2560) and the Human Research Ethics Committee of BhumiBol Adulyadej Hospital. The clinical trial number was MTU-EC-ES-4-013/60. Informed consents/assents were obtained from the children and parents.

GAN Core Questionnaires

GAN 2016 standardized written core questionnaires for AR modifying from ISAAC questionnaires were used in this study. The questionnaires were translated and back-translated into the Thai language by three independent linguistic-proficient individuals. Demographic questions included the participant’s name, age, date of birth, school (for the adolescents and children), sex, and date of interview. Questionnaires were coded by using a unique number for each center, school, and participant to ensure confidentiality and to link the questionnaires between the adults and children. The written core questionnaires, used in GAN, had a question about doctor-diagnosed asthma, rhinitis, and eczema added. The core questions were both sensitive and specific, and they had good content, construct, concurrent, and predictive validity. The environmental risk factor questionnaires, developed for ISAAC phase III, were expanded for use in this study. Height and weight measurements were taken by the fieldworkers in schools.

Definitions of AR, Rhinitis, and Hay Fever

The standardized core symptom questionnaire was the same as that used in ISAAC phase I and comprised of six questions on symptoms relating to rhinitis or rhinoconjunctivitis. These questions were as follows:

1. Have you (has your child) ever had a problem with sneezing or a runny or blocked nose when you (he or she) DID NOT have a cold or “the flu”?
2. In the past 12 months, have you (has your child) had a problem with sneezing or a runny or blocked nose when you (he or she) DID NOT have a cold or “the flu”?
3. In the past 12 months, has this nose problem been accompanied by itchy/watery eyes?
4. In which of the past 12 months did this nose problem occur? (Month names listed)
5. In the past 12 months, how much did this nose problem interfere with your (child’s) daily activities? (Not at all, a little, a moderate amount, a lot)
6. Have you (has your child) ever had hay fever?

Question 2 was used to estimate the prevalence of current rhinitis; question 3 was used to estimate the prevalence of current conjunctivitis; and question 6 was used to estimate the prevalence of “hay fever ever.” Questions 2 and 3 were combined to assess current rhinoconjunctivitis symptoms or current AR. Questions 2 and 3 and the answer “A LOT” to question 5 were used to assess the prevalence of severe rhinoconjunctivitis symptoms or severe AR.

Sample Size

A sample size of 2,654 is needed to estimate the prevalence of questionnaire-based AR of 10% for children of each age group with margin errors of ±1.5% and type one error of 0.01. The total sample size of 6,834 was accounted for the non-response rate of 30%.

Data Collection and Analysis

Data were collected from July 2017 to February 2018. Statistical analyses were carried out using STATA/SE software (Stata/SE 14 for Windows, StataCorp LP, College Station, TX, USA). Binomial confidence intervals (CIs) on proportions with rhinitis and rhinoconjunctivitis were calculated. The multivariable logistic regression model was used to conduct exploratory analysis for risk factors of AR. The model included
age, sex, family history of allergy, birth weight, paracetamol, antibiotics, truck traffic, breastfeeding, farm animals, cat and dog exposure, air pollution, tobacco, BMI, diet, cooking fuels, migration, and number of older and younger siblings to estimate the magnitude of the association by calculating adjusted odds ratios with their 95% CIs.

Results

The prevalence of questionnaire-based symptoms of rhinitis stratified by age group is shown in Table 1. The prevalence of current rhinitis in children aged 6–7 years and 13–14 years was 38.2% (95%CI: 36.5–39.9%) and 48.8% (95%CI: 47.0–50.5%), respectively. The prevalence of current rhinitis in all children was 43.6% (95%CI: 42.4–44.8%). Concomitant eye symptoms were reported at 16.3%. The prevalence of current AR in children aged 6–7 years and 13–14 years was 15.0% (95%CI: 13.8–16.3%) and 17.5% (95%CI: 16.2–18.8%), respectively. The prevalence of current AR in all children was 16.3% (95%CI: 15.4–17.2%).

Although the term so-called “hay fever” does not exist in the Thai language, 27.4% indicated that they suffered from “allergy to the air,” a common term denoting hay fever in Thailand.

Patterns of rhinitis symptoms of children in Bangkok were of the perennial type. The prevalence of severe AR in children aged 6–7 years and 13–14 years was 1.0% (95%CI: 0.6–1.3%) and 1.9% (95%CI: 1.4–2.4%), respectively. The prevalence of severe AR in all children was 1.5% (95%CI: 1.2–1.7%). There were strong associations with other allergic diseases: 27.1% of children with AR had asthma and 24.6% had eczema.

A parental history of atopy including asthma (p = 0.025, OR = 1.50, 95%CI = 1.05–2.13), AR (p < 0.001, OR = 1.43, 95%CI = 1.10–1.71), and eczema (p < 0.01, OR = 1.56, 95%CI = 1.29–1.88) was significantly related to current AR. Current use of paracetamol was associated with current AR (p < 0.001, OR = 1.64, 95%CI = 1.30–2.08). Exercise was associated with current AR (p < 0.001, OR = 1.49, 95%CI = 1.29–1.71). Only current cat exposure was associated with current AR (p = 0.008, OR = 1.28, 95%CI = 1.07–1.54). The frequency of truck traffic on the street of residence was positively associated with current AR; comparison of both the occasional truck traffic group (p = 0.002, OR = 1.28, 95%CI = 1.10–1.50) and the always truck traffic group (p < 0.001, OR = 1.73, 95%CI = 1.41–2.11) to the never truck traffic group is shown in Tables 2 and 3.

* Multivariable logistic regression model
Concerning the age group of 6–7 years, parental history of AR and eczema was significantly related to current AR (AR: p < 0.001, OR = 1.71, 95% CI = 1.35–2.17; eczema: p < 0.001, OR = 1.83, 95% CI = 1.42–2.35). Lower respiratory tract infection (LRTI) in the first year of life was positively associated with current AR (p = 0.001, OR = 1.86, 95% CI = 1.34–2.59). Parental reported breastfeeding (six months) was positively associated with current AR (p = 0.019, OR = 1.28, 95% CI = 1.04–1.57). The frequency of truck traffic on the street of residence was positively associated with the prevalence of current AR for both the occasional truck traffic group (p = 0.007, OR = 1.39, 95% CI = 1.09–1.76) and the always truck traffic group (p < 0.001, OR = 1.92, 95% CI = 1.42–2.58), as shown in Tables 2 and 3.

In the children aged 13–14 years, parental history of atopy was not significantly related to an increased risk of current AR. Current use of paracetamol, however, was associated with increased risk of current AR (p = 0.004, OR = 1.57, 95% CI = 1.16–2.14). Only current cat exposure was associated with increased risk of current AR (p = 0.015, OR = 1.32, 95% CI = 1.05–1.64). The frequency of truck traffic on the street of residence was also positively associated with the prevalence of current AR in both the occasional truck traffic group (p = 0.032, OR = 1.25, 95% CI = 1.02–1.54) and the always truck traffic group (p < 0.001, OR = 1.62, 95% CI = 1.24–2.13), as shown in Tables 2 and 3.

Discussion

The results from our study showed the prevalence of current AR in the children aged 6–7 years to be 15.0%. When compared to ISAAC phase III in the Bangkok area at 13.4%, there was a slightly but significantly increased prevalence in the younger age group (p = 0.006). In this study, the prevalence of current AR in the 13–14-year age group was 17.5%. This decrease was significant when compared to ISAAC phase III in Bangkok (23.9%, p = 0.006). The mean global prevalence of current AR in both age groups was 9.1% and 16%, respectively, in which the Asia-Pacific prevalence was 5.8% and the ISAAC phase III prevalence was 14.5%. The results of our study so far show a higher percentage in both prevalences.

Our study confirms that parental atopy is a risk factor for the development of AR. These results are consistent with the findings of other studies. Both genetic and environmental factors play important roles in the etiology of AR. It is likely that there is a multilevel interaction between genetic and environmental factors.

This study did not find any association between antibiotic use in the first year of life and later AR. We found a positive relation between current consumption of paracetamol and the prevalence of current AR. There is a dose-related association between acetaminophen use and AR in children. The association of paracetamol with allergic disease is possible due to the depletion of glutathione. This is a result of the pharmacokinetics of this drug, leaving the respiratory mucosa with inadequate antioxidant protection. This mechanism could explain the possible association between paracetamol consumption and the prevalence of the symptoms of rhinitis in our patients.

Our results show that LRTI in the first year of life was positively associated with current AR. Respiratory infections are among the major causes of hospitalization and pediatric medical consultation, and they are directly associated with mortality in children. Allergic children showed a significantly higher number of respiratory infections in comparison with the non-allergic group. Epidemiological studies have investigated significant relationships between AR and LRTI.

In phase III of ISAAC, there was no consistent association between breastfeeding in the first year of life and rhinoconjunctivitis in 6–7-year-old children. However, breastfeeding was associated with reduced prevalence of current symptoms of severe rhinoconjunctivitis. Our results suggest that breastfeeding (six months) was associated with current AR. Several studies have shown that breastfeeding in developing countries is associated with protection against infections, particularly gastric infection and diarrhea. The immunological properties of breast milk are significant contributing factors to infant health in poor countries. Breastfeeding is therefore rightly promoted by authorities such as the World Health Organization.

ISAAC phase III showed that early-life exposure to cats is a risk factor for symptoms of rhinoconjunctivitis in 6–7-year-old children. Current exposure to cats and dogs combined, and only to dogs, is a risk factor for symptom reporting by 13–14-year-old adolescents worldwide. The Melbourne Atopy Cohort study (MASC) showed no evidence that exposure to cats and dogs at birth increases the risk of allergic disease in high-risk children. The Childhood Origins of ASThma (COAST) showed associations between allergen-specific sensitization and rhinitis. At one year, sensitization to cats was the only aeroallergen associated with an increased risk of rhinitis at 6 years of age. At age 6 years, sensitization to all allergens tested except cockroach was associated with concurrent rhinitis.

In this study, we found a positive global relationship between childhood symptoms of current AR and self-reported frequency of truck traffic on the street of residence. The associations were remarkably similar in different parts of the world in the two age groups studied and when using a self-completed questionnaire and a parent-completed questionnaire for 6–7-year-old children. A recent study from Italy found that self-reported traffic density in the area of residence was clearly associated with nitrogen dioxide, which was 39 µg/m³ when self-reported traffic was “absent,” 44 µg/m³ when “low,” 48 µg/m³ when “intermediate,” and 52 µg/m³ when “high.” First, there are now several published studies that have used objective measures of exposure and effect and found similar relationships between truck traffic exposure or other measures of exposure to vehicular traffic and respiratory and allergic symptoms in children. Second, these studies were conducted mostly in Western Europe and North America, and in ISAAC phase III the associations found in these regions were not different from those found in other parts of the world. One could argue that concern about possible adverse effects on respiratory health by traffic fumes is different in different parts of the world, so one would not expect to see a universal association if responder bias played much of a role. Third, the associations were similar for the
13–14-year-olds and the 6–7-year-olds, despite the fact that the teenagers completed the questionnaires themselves, whereas the parents completed the questionnaires for the 6–7-year-olds. We can only speculate about what factors influence the remaining heterogeneity of exposure–response relationships between participating centers. There is experimental evidence to support that diesel particles may enhance allergic sensitization to common inhalant allergens.\(^3\)

The major strengths of our study included standardized written core questionnaires (GAN 2016) for AR modified from ISAAC questionnaires, a well-established and standardized protocol, and a high response rate. One limitation of our study is that it is cross-sectional, which limits our ability to determine causation. Another limitation is that symptoms of AR were self-reported in the questionnaire; therefore, we could not confirm with physical examination and laboratory investigations.

In conclusion, our study shows that the prevalence of AR remained high in both age groups. Our data confirm that a family history of atopy, LRTI in the first year of life, breastfeeding (six months), current paracetamol use, exercise, current cat exposure, and truck traffic on the street of residence are important and significant risk factors for AR symptoms. This study may serve as evidence-based health education for parents to reduce the prevalence of AR by proper management of common disease (current use of paracetamol, LRTI in the first year of life, asthma, eczema) and environmental control (pets and truck traffic on the street of residence). More detailed studies are needed on the risk factors of AR.

Prevalence and risk factors of allergic rhinitis in children in the Bangkok area

A novel allergen-specific therapy with regulatory T cells induced by CD40-silenced dendritic cells

Motohiko Suzuki, Makoto Yokota, Shinya Ozaki, Yoshihisa Nakamura

Abstract

Background: We previously reported that dendritic cells (DCs) transfected with CD40 siRNA and pulsed by ovalbumin (OVA) (CD40-silenced OVA DCs) inhibited allergic responses through facilitation of regulatory T cells (Tregs). However, to our knowledge, no prior study has examined allergen-specific therapy by administration of siRNA-induced Tregs for the control of allergy.

Objective: We aimed to investigate the effect of Tregs induced in vitro on allergic responses and symptoms in vivo.

Methods: Mice were treated with Tregs (OVA DCs-induced Tregs) induced by CD40-silenced OVA DCs or Tregs (nonantigen DCs-induced Tregs) induced by DCs transfected with CD40 siRNA and pulsed with no antigen, and the effects of these Tregs on allergic responses were estimated.

Results: Administration of nonantigen DCs-induced Tregs prevented not only OVA-induced allergy but also keyhole limpet hemocyanin-induced allergy. Administration of OVA DCs-induced Tregs significantly reduced the number of sneezes and nasal rubbing movements, eosinophilia in the nasal mucosa, and the level of OVA-specific IgE in mice with OVA-induced allergy, compared with CD40-silenced nonantigen DC-induced Tregs in numbers 20 times greater, even in mice with established allergic rhinitis. Furthermore, Tregs induced by CD40-silenced DCs pulsed with Cry j 1, a major allergen of Japanese cedar pollen, inhibited Japanese cedar-induced allergy.

Conclusions: This study shows for the first time that both antigen-independent Tregs and antigen-specific Tregs can be induced by siRNA, and that therapy with siRNA-induced Tregs inhibits allergic responses and symptoms. It also shows that antigen-specific Tregs have more potent effects in inhibiting allergic responses than antigen-nonspecific Tregs.

Key words: Regulatory T cells, Allergy, CD40, siRNA, Dendritic cells.

Introduction

CD40 is an integral membrane protein in dendritic cells (DCs) that activates T cells. Blockade of the CD40-CD40L interaction is a potent tolerance-inducing strategy, while the inhibition of this interaction suppresses T cell responses and generates regulatory T cells (Tregs).

RNA interference using small interfering RNA (siRNA) induces specific silencing of gene expression, and is a potent, selective, and easy method. Andrew Fire and Craig Mello received the Nobel Prize in Medicine for this discovery. Silencing gene expression by siRNA is more useful and promising than conventional silencing strategies by gene or antibody, such as blocking antibody, blocking protein, antisense oligonucleotide, and ribozymes.

We previously reported that vector expressing siRNA specific for CD40 (CD40 siRNA) inhibits allergic responses not only as a means of prevention but also as treatment. However, direct administration of vector expressing siRNA may induce complications, because it is an antigen-nonspecific therapy and the vector or siRNA may change immune responses in vivo. We also showed that administration of CD40-silenced antigen-specific dendritic cells (DCs), transfected with CD40 siRNA but not vector CD40 siRNA and pulsed by antigen in vitro,
inhibited allergic responses and symptoms antigen-specifically. However, CD40-silenced antigen-specific DCs may lead to unexpected complications in vivo, since siRNA in CD40-silenced DCs may cause unexpected problems. We additionally documented that CD40-silenced DCs induce facilitation of CD4⁺CD25⁺ Tregs in vivo. Furthermore, induction of Tregs by CD40-silenced DCs is not always the same by the conditions in vivo. Considering this, direct administration of antigen-specific CD4⁺CD25⁺ Tregs, induced by siRNA in vitro, is an attractive strategy for safer and more effective control of allergic diseases. To our knowledge, however, therapy with antigen-specific CD4⁺CD25⁺ Tregs induced by siRNA in vitro has not been reported for the control of allergy, and its usefulness is not known.

The generation of Tregs with anti-CD3/CD28 antibodies in vitro has been reported. However, these are not antigen-specific Tregs. Antigen-specific Tregs are attractive for the treatment of allergy, since antigen-non-specific Tregs may affect various immune responses and contribute to a range of diseases, including cancer. It has been also reported that induced-Tregs generated by anti-CD3/CD28 antibodies differ from those induced by physiology-like activation with antigen/antigen-presenting cells.

In this study, we examined the effect on allergic diseases of CD4⁺CD25⁺ Tregs induced by antigen-specific DCs transfected with siRNA in vitro. The results showed that administration of ovalbumin (OVA)-specific CD4⁺CD25⁺ Tregs, induced by DCs transfected with CD40 siRNA and pulsed with OVA in vitro, inhibited allergic responses and symptoms in mice with allergic rhinitis, and that CD40-silenced DCs pulsed without antigen induced antigen-non-specific Tregs. It was also shown that antigen-specific Tregs were more potent in inhibiting allergic responses and symptoms than antigen-non-specific Tregs.

**Methods**

**Generation of bone marrow-derived DCs and gene silencing by siRNA**

DCs were generated from bone marrow progenitor cells, as previously described. These DCs were transfected with transfection reagent alone (No siRNA DCs), siRNA (Control siRNA) specific to the Luciferase gene GL2 Duplex siRNA (Control DCs), or siRNA (CD40 siRNA, UUCUCAGCCCGAG UGGAACA) specific to CD40. DCs transfected with CD40 siRNA were pulsed with OVA (CD40-silenced OVA DCs) or without OVA (CD40-silenced nonantigen DCs), as described previously. DCs transfected with CD40 siRNA were also pulsed with Cry j 1, a major allergen of Japanese cedar (Cryptomeria japonica) pollen, (CD40-silenced Cry j 1 DCs) by the same method. Cry j 1 was purified by the method previously reported.

**Generation of Tregs in vitro**

Mouse naïve CD4⁺ T cells were isolated from splenic cells of six to eight-week-old male BALB/c mice using a Mouse naïve CD4⁺ T Cell Isolation Kit (R&D Systems, CA). Mouse naïve CD4⁺ T cells (3 × 10⁶/mL) were co-cultured with 6 × 10⁶/mL No siRNA DCs, Control DCs, CD40-silenced nonantigen DCs, CD40-silenced OVA DCs, or CD40-silenced Cry j 1 DCs for 5 days in 2 mL of complete medium, RPMI 1640 supplemented with 2 mM L-glutamine, 100 U/mL penicillin, 100 μg/mL streptomycin, 50 μM 2-ME, and 10% FCS supplemented with TGF-β (5 ng/mL) and IL-2 (50 IU/mL). CD4⁺CD25⁺ T cells were collected using a MACS negative CD4 isolation kit and anti-CD25 MACS beads (Miltenyi Biotec, Bergisch Gladbach, Germany).

**Immunization and Treatment**

Six to eight week-old male BALB/c mice (Japan SLC Inc., Shizuoka, Japan) were injected intravenously with PBS alone, Tregs (4 × 10⁶ or 4 × 10⁷ cells/mouse) induced by CD40-silenced nonantigen DCs, or Tregs (4 × 10⁷ cells/mouse) induced by CD40-silenced OVA DCs on day 1. Mice were also injected intraperitoneally (i.p.) with 4 mg Al(OH)₃, and 10 μg ovalbumin (OVA) twice on days 2 and 15. Each group consisted of five mice. The same mice were challenged intranasally (i.n.) on days 21 through 27 with OVA (100 μg). Samples were collected on day 28.

In the second experiment, the protocol was the same as in the above experiment except that mice received PBS alone, Tregs (4 × 10⁶ or 4 × 10⁷ cells/mouse) induced by CD40-silenced nonantigen DCs, or Tregs (4 × 10⁷ cells/mouse) induced by CD40-silenced OVA DCs and that mice were injected i.p. with 4 mg Al(OH)₃, and keyhole limpet hemocyanin (KLH), but not OVA, on days 2 and 15 and challenged i.n. on days 21 through 27 with KLH.

In the third experiment, mice were sensitized with OVA (10 μg) and 2 mg Al(OH)₃ intraperitoneally on days 1 and 14, and then the same mice were challenged intranasally with OVA (100 μg) on days 18 through 24. Intravenous administration of PBS alone, Tregs induced by CD40-silenced nonantigen DCs (4 × 10⁵ or 8 × 10⁵ cells/mouse), or Tregs by CD40-silenced OVA DCs (4 × 10⁵ cells/mouse), was performed on day 26. These mice were then re-challenged intranasally on days 27 through 32 with OVA (100 μg).

In the fourth experiment, mice were sensitized with Cry j 1 (3 μg) and 2 mg Al(OH)₃ intraperitoneally on days 1 and 14, and then the same mice were challenged intranasally with Cry j 1 (2 μg) on days 18 through 24. Intravenous administration of PBS alone, Tregs induced by CD40-silenced nonantigen DCs (8 × 10⁶ cells/mouse), or Tregs by CD40-silenced Cry j 1 DCs (4 × 10⁵ cells/mouse), was performed on day 26. These mice were then re-challenged intranasally on days 27 through 32 with Cry j 1 (3 μg).

This study was approved by Research Ethics Committee in Nagoya City University. Mice were housed in an environmentally-controlled animal facility at Nagoya City University in Japan. The protocols were in accordance with the Guidelines for Care and Use of Animals of Nagoya City University. Every effort was made to minimize the discomfort of the animals.

**Cry j 1-specific T cell response**

CD4⁺CD25 T cells and CD11c cells were isolated from spleen using MACS beads (Miltenyi Biotec). Spleen CD4⁺CD25 T cell (2 × 10⁶ cells/mL) and DC (2 × 10⁶ cells/mL) suspensions were cultured for 72 h and stimulated with 10 μg/mL Cry j 1 antigen.
OVA-specific T cell response

Spleenic cells isolated by gradient centrifugation over Ficoll-Paque (Amersham Pharmacia Biotech, Uppsala, Sweden) were cultured in 96-well plates at a concentration of 4 × 10^5 cells/well for 72 h in the presence of 100 µg/mL OVA antigen.

Measurement of IL-2 production

Spleen CD4+CD25 T cell (2 × 10^6 cells/mL) and DC (2 × 10^6 cells/mL) transduced with or without CD40 siRNA suspensions were cultured for 72 hours, stimulated with 10µg/mL Cry j 1. Quantities of IL-2 cytokines in the culture supernatants were determined by using a sandwich ELISA. Plates were coated with anti-mouse IL-2 (BioLegend, San Diego, CA). The culture supernatant was then added, and the plates were incubated with the second antibody of biotinylated anti-mouse IL-2 (BioLegend). Standard curves were generated by using recombinant cytokines.

Measurement of OVA-specific, KLH-specific, and Cry j 1-specific IgE in sera

Titers of specific IgE were measured by ELISA. Briefly, ELISA plates were coated with anti-mouse IgE monoclonal antibody (Tamas, Tokyo, Japan). Non-specific binding was blocked and sera were added. After washing with wash buffer, biotinylated OVA, KLH, or Cry j 1 was added to the well. The plates were then incubated with avidin-peroxidase at 37°C for an hour after washing. The TMB microwell peroxidase substrate system (KPL, Gaithersburg, MD) was used, and optical density (O.D.) was measured at 450 nm.

Nasal allergic symptoms

Immediately after the last nasal challenge, the number of sneezes and nasal rubbing movements was counted for 20 min according to the method previously reported.11

Pathology

The heads were decalcified and sectioned. Three micrometer thick sections of nasal tissue were stained with Luna staining. The number of eosinophils in the nasal mucosa of the nasal septum was counted microscopically in a field of view at 400× magnification. The observer was blinded to treatment when counting the number of eosinophils.

Statistical analysis

Data are expressed as means ± SEM. Statistical comparisons between groups were performed using one-way ANOVA followed by the Newman-Keuls Test. Differences with P-values less than 0.05 were considered significant.

Results

Prevention of OVA-induced allergy with CD40-silenced DC-induced OVA Tregs

We investigated whether Tregs induced by CD40-silenced OVA DCs in vitro could prevent OVA-induced allergy. Mice that received PBS, CD40-silenced nonantigen DC-induced CD4+CD25+ cells, or CD40-silenced OVA DC-induced CD4+CD25+ cells were sensitized and challenged with OVA as described in Methods (treatment on day 1, sensitization on days 2 & 15, challenge on days 21-27, sample collection on day 28). The number of sneezes and nasal rubbing movements was counted immediately after the last nasal challenge to examine the effect of these T cells on nasal allergic symptoms. CD40-silenced OVA DC-induced Tregs significantly decreased the number of sneezes and nasal rubbing movements compared with the other groups (Figure 1A and B). Although CD40-silenced nonantigen DC-induced T cells at a concentration of 4 × 10^6 cells/mouse did not reduce these symptoms, CD40-silenced nonantigen DC-induced T cells at levels 10 times greater and more (4 × 10^7 cells/mouse and 8 × 10^6 cells/mouse) significantly inhibited these symptoms. However, there were no significant differences in symptom inhibition between CD40-silenced nonantigen DC-induced Tregs at levels of 4 × 10^6 cells/mouse and 8 × 10^6 cells/mouse.

Next, the number of eosinophils in the nasal septum was counted to evaluate eosinophilia, which is associated with allergic symptoms and allergic responses in the nose. The number of eosinophils infiltrating the nasal mucosa in mice injected with Tregs induced by CD40-silenced OVA DCs was

Figure 1. Prevention effects of allergy by CD4+CD25+ cells induced by CD40-silenced OVA DCs.

Five mice were injected intraperitoneally and challenged intranasally with OVA after treatment of PBS alone, CD40-silenced nonantigen DC-induced CD4+CD25+ cells (CD40 Non, 4 × 10^6 “X1”, 4 × 10^6 “X10”, or 8 × 10^6 “X20”, cells/mouse), or CD40-silenced OVA DC-induced CD4+CD25+ cells (CD40 OVA, 4 × 10^6 cells/mouse). The number of sneezes (A) and nasal rubbing movements (B) was counted after the last nasal challenge.
Tregs to treat allergic diseases

The number of eosinophils

Figure 1. (Continued)

(C) Eosinophilia of the nasal septum. (D) The level of OVA-specific IgE in sera. The level of IL-4 (E) and IL-5 (F) production from splenic splenocytes stimulated by OVA was measured by ELISA. ** P < 0.01 versus groups of PBS alone and CD40-Non X1. ## P < 0.01 versus groups of CD40-Non (X10, X20). Experiments were repeated 3 times with similar result.

significantly fewer than that in mice with PBS alone or Tregs induced by CD40-silenced nonantigen DCs (Figure 1C). CD40-silenced nonantigen DC-induced Tregs at levels of $4 \times 10^6$ cells/mouse or $8 \times 10^6$ cells/mouse also significantly inhibited this eosinophilia, whereas CD40-silenced nonantigen DC-induced Tregs at the level of $4 \times 10^5$ cells/mouse did not (Figure 1C).

We also measured OVA-specific IgE in sera by ELISA, since IgE is associated with allergic reactions. CD40-silenced nonantigen DC-induced Tregs at levels of $4 \times 10^6$ or $8 \times 10^6$ cells/mouse also significantly suppressed the level of OVA-specific IgE, although CD40-silenced nonantigen DC-induced Tregs at the level of $4 \times 10^5$ cells/mouse/mouse did not. Tregs produced by CD40-silenced OVA DCs inhibited OVA-specific IgE significantly more than the other groups (Figure 1D). These data suggest that Tregs induced by CD40-silenced OVA DCs prevent production of OVA-specific IgE.

IL-4 and IL-5 play important roles in the development of allergic diseases. In order to investigate the effect of Tregs induced by CD40-silenced OVA DCs on cytokine production, we measured the production of IL-4 and IL-5 from splenic T cells stimulated with OVA in vitro. There were no significant differences between mice received PBS alone and CD40-silenced nonantigen DC-induced Tregs at levels of $4 \times 10^6$ cells/mouse in the productions of IL-4 and IL-5. The levels of IL-4 and IL-5 produced in mice that received Tregs induced by CD40-silenced OVA DCs were significantly lower than those in mice that received PBS or Tregs induced by CD40-silenced nonantigen DCs (Figure 1E and F). This suggests that OVA-specific Tregs suppress the production of Th2 cytokines, which may contribute to the prevention of allergy.

No preventive effect of Tregs induced by CD40-silenced OVA DCs on KLH-induced allergy

To investigate antigen specificity, we examined whether Tregs induced by CD40-silenced OVA DCs in vitro can inhibit allergic responses and symptoms caused by KLH. Mice received PBS, CD40-silenced nonantigen DC-induced Tregs, or CD40-silenced OVA DC-induced Tregs were sensitized and challenged with KLH as described in Methods (treatment on day 1, sensitization on days 2 & 15, challenge on days 21-27, sample collection on day 28). Administration of Tregs induced by CD40-silenced OVA DCs did not significantly inhibit the number of nasal sneezes, nasal rubbing movements, or eosinophils at the nasal septum and the level of KLH-specific IgE in sera compared with mice that received PBS alone (Figure 2A-D). These findings suggest that Tregs induced by CD40-silenced OVA DCs inhibit allergen reactions and symptoms in an antigen-specific manner.

Administration of CD40-silenced nonantigen DC-induced Tregs ($4 \times 10^6$ cells/mouse) inhibited the number of nasal sneezes, nasal rubbing movements, and eosinophils at the nasal mucosa and KLH-specific IgE levels in sera compared with the other groups (Figure 2A-D). These results suggest
Figure 2. No allergy prevention effect from CD4⁺CD25⁺Tregs induced by CD40-silenced OVA DCs.
Five mice were injected intraperitoneally and challenged intranasally with KLH after treatment with PBS alone, CD40-silenced nonantigen DC-induced CD4⁺CD25⁺ cells (CD40⁻ Non, 4 × 10⁵ “X1” or 4 × 10⁶ “X10” cells/mouse), or CD40-silenced OVA DC-induced CD4⁺CD25⁺ cells (CD40 OVA, 4 × 10⁵ “X1” or 4 × 10⁶ “X10” cells/mouse). The numbers of sneezes (A) and nasal rubbing movements (B) were counted after the last nasal challenge. (C) Eosinophilia of the nasal septum. (D) The level of KLH-specific IgE in sera. ** P < 0.01 versus groups of PBS alone, CD40⁻ Non X1, and CD40⁻ OVA (X1, X10). Experiments were repeated 3 times with similar result.

Figure 3. Therapeutic effects of CD4⁺CD25⁺Tregs induced by CD40-silenced OVA DCs in vitro on established allergic rhinitis.
Five mice with OVA-induced allergic rhinitis were treated with PBS alone, CD40-silenced nonantigen DC-induced CD4⁺CD25⁺ cells (CD40⁻ Non, 4 × 10⁵ “X10” or 8 × 10⁶ “X20” cells/mouse), or CD40-silenced OVA DC-induced CD4⁺CD25⁺ cells (4 × 10⁵ “CD40- OVA X1” cells/mouse). The number of sneezes (A) and nasal rubbing movements (B) was counted after the last nasal challenge.
that CD40-silenced nonantigen DC-induced Tregs are not antigen-specific.

**Therapeutic effects of Tregs induced by CD40-silenced OVA DCs on mice with established OVA-induced allergic rhinitis**

Mice with established allergic rhinitis were treated with PBS alone, CD40-silenced nonantigen DC-induced Tregs, or CD40-silenced OVA DC-induced Tregs. After treatment, nasal re-challenge with OVA was performed (sensitization on days 1 & 14, nasal challenge on days 18-24, treatment with Tregs on day 26, nasal re-challenge on days 27-32, sample collection on day 33). The number of sneezes and nasal rubbing movements on day 24 was significantly higher than on day 17 (data not shown). Eosinophils in the nasal septum were seen on day 24, although no eosinophilia was found on day 17 (data not shown). These results suggest that mice were suffering from allergic rhinitis on day 24. There were no significant effects on the number of sneezes, nasal rubbing movements, or eosinophils in the nasal mucosa, or the level of OVA-specific IgE in sera, even when CD40-silenced nonantigen DC-induced Tregs (8 × 10⁶ cells/mouse) were injected (Figure 3A-D).

Tregs induced by CD40-silenced OVA DCs in vitro significantly reduced the number of sneezes, nasal rubbing movements, and eosinophils in the nasal mucosa, and the level of OVA-specific IgE in sera, compared with the other groups, PBS alone, and Tregs induced by CD40-silenced nonantigen DCs (Figure 3A-D). These findings suggest that Tregs induced by CD40-silenced OVA DCs are therapeutically useful even for mice with established allergic rhinitis.

**Immune regulatory properties of Tregs induced by DCs**

Next, we investigated Tregs induced by CD40-silenced DCs (CD40-silenced Cry j 1 DCs) pulsed with Cry j 1 but not OVA, because OVA is a food allergen but not aeroallergen. Cry j 1 is one of the major allergens of Japanese cedar pollen which cause severe allergic diseases in Japan. Bone marrow-derived DCs were transfected with CD40 siRNA or Control siRNA (Control DCs). DCs transfected with CD40 siRNA were pulsed

with Cry j 1 (CD40-silenced Cry j 1 DCs) or no antigen (CD40-silenced nonantigen DCs). Naïve T cells, separated from splenic T cells in naïve mice as described in Methods, were co-cultured with Control DCs, CD40-silenced nonantigen DCs, or CD40-silenced Cry j 1 DCs. Although we assessed the number of CD4⁺CD25⁺ cells were induced from 3 × 10⁶ naïve CD4⁺ cells, the number of CD4⁺CD25⁺ cells induced by CD40-silenced Cry j 1 DCs or CD40-silenced nonantigen DCs were significantly higher than that by Control DCs. (Figure 4A). The percentage of CD25⁺Foxp3⁺ cells in CD4⁺ T cells induced by CD40-silenced nonantigen DCs and CD40-silenced Cry j 1 DCs were significantly higher compared with those induced by Control DCs (Figure 4B). And we investigated whether CD4⁺CD25⁺ cells induced by CD40-silenced Cry j 1 DCs could affect IL-2 production in order to examine the mechanism of Treg induction, since the association between IL-2 production and Treg expansion has been reported.20,21 Cry j 1-specific T cell response was generated by a co-culture of DCs and CD4⁺CD25⁺ T cells isolated from the spleen in mice sensitized with Cry j 1 antigen. Quantity of IL-2 in the supernatant was measured by ELISA. Consequently, IL-2 production was significantly inhibited by CD40-silenced nonantigen DCs or CD40-silenced Cry j 1 DCs (Figure 4C).

**Therapeutic effects of Tregs induced by CD40-silenced Cry j 1 DCs on mice with established Cry j 1-induced allergic rhinitis**

We assessed the effects of siRNA-induced Tregs on allergic diseases caused by aeroallergen, Japanese cedar pollen. Mice with allergic rhinitis were treated with PBS alone, CD40-silenced nonantigen DC-induced Tregs, or CD40-silenced Cry j 1 DC-induced Tregs. After treatment, nasal re-challenge with Cry j 1 was performed (sensitization on days 1 & 14, nasal challenge on days 18-24, treatment with Tregs on day 26, nasal re-challenge on days 27-32, sample collection on day 33). No eosinophilia in the nasal septum was found on day 17, whereas eosinophilia was seen on day 24 (data not shown). The numbers of sneezes and nasal rubbing movements on day 24 were significantly higher than those on day 17 (data not shown). These suggest that allergic rhinitis was established on day 24. After treatment with CD40-silenced nonantigen DC-induced Tregs, there were no significant effects on the number of sneezes, nasal rubbing movements, eosinophilia in the nasal mucosa, and

---

**Figure 5. Therapeutic effects of CD4⁺CD25⁺Tregs induced by CD40-silenced Cry j 1 DCs in vitro on established allergic rhinitis.**

Five mice with Cry j 1-induced allergic rhinitis were treated with PBS alone, CD40-silenced nonantigen DC-induced CD4⁺CD25⁺ cells (8 × 10⁶ cells/mouse, CD40 Non Tregs) or CD40-silenced Cry j 1 DC-induced CD4⁺CD25⁺ cells (4 × 10⁵ cells/mouse, CD40-Cry j 1 Tregs). The number of sneezes (A) and nasal rubbing movements (B) was counted after the last nasal challenge. (C) Eosinophilia of the nasal septum. (D) The level of Cry j 1-specific IgE in sera. ** P < 0.01 versus group of PBS alone, ## P < 0.01 versus group of CD40 Non Tregs. Experiments were repeated 3 times with similar result.
the level of Cry 1-specific IgE in sera (Figure 5A-D). However, Tregs induced by CD40-silenced Cry 1 DCs in vitro significantly reduced the number of sneezes, nasal rubbing movements, and eosinophilia in the nasal mucosa, and the level of Cry 1-specific IgE in sera, compared with other groups, PBS alone, and Tregs induced by CD40-silenced nonantigen DCs (Figure 5A-D). These findings suggest that Tregs induced by CD40-silenced Cry 1 DCs are therapeutically useful for mice with allergic rhinitis caused by Japanese cedar pollen.

Discussion
Administration of Tregs induced by CD40-silenced nonantigen DCs before sensitization significantly reduced allergic responses and symptoms not only in OVA-induced allergy but also in KLH-induced allergy. These results suggest that Tregs induced by CD40-silenced nonantigen DCs are antigen-non-specific Tregs. Patients who suffer from sensitization to multiple allergens are increasing.23 Antigen-specific therapy for these patients is not easy, nor is it applicable for patients with an unknown causative allergen. Thus, CD40 silenced nonantigen DC-induced Tregs may be an alternative, antigen-independent therapy for the prevention of allergic diseases.

Although blockade of CD40-CD40L interaction induce Tregs,24,25 the underlying mechanism of Treg expansion by blockade of CD40-CD40L is not known.24 However, low-dose IL-2 expands CD4+ regulatory T cells with a suppressive function in vitro.26 Both blockade of B7-CD28 and CD40-CD40L also activated Foxp3+ regulatory T cells and reduced IL-2 production.20 When CD25+ CD4+ T cells compete with other cells for IL-2, CD4+CD25+ T cells further up-regulate the CD25 (IL-2R alpha chain).21 And Vogel et al.20 assumed that the low amount of IL-2 is enough for the survival of CD4+Foxp3+ cells, but not enough for the survival of CD4+Foxp3+ cells. This study showed that blockade of only CD40-CD40L pathway inhibited IL-2 productions. These suggest that blockade of CD40-CD40L induces expansion of CD4+Foxp3+ Tregs through reduction of IL-2 production.

We previously reported that CD40-silenced OVA DCs inhibited allergic reactions and symptoms. However, CD40-silenced OVA DCs may induce unexpected problems in vivo. CD40 siRNA may go out of DCs and induce problems such as inhibition of CD40 gene on other cells, interferon response, and off-target effect, although these have been not reported. If deficiency of CD40-CD40L interaction occurs in vivo, this may lead susceptibility to infection26,27 like hyper IgM syndrome.28 dsRNA, less than 30 bp in length, are generally believed to avoid interferon responses.29 However, interferon response should be paid attention to even in siRNA, since siRNA could interfere response30,31 and since the threshold of dsRNA length to induce interferon response varies by cell types.29 In future, various Treg phenotype may be revealed. Even if siRNA-induced Tregs include various Treg phenotype, it may be possible to collect only specific phenotype before administration in time to come. The advantages of this novel therapy with siRNA-induced Tregs presented herein include: 1) no interferon responses caused by siRNA; 2) no off-target effects by siRNA; 3) no inhibition of CD40 gene expression in vivo by CD40 siRNA; 4) no unexpected problems by siRNA or siRNA-transfected DCs; 5) higher stability in the numbers of siRNA-induced Tregs administered (induction of Tregs by CD40-silenced DCs is not always the same by the conditions in vivo), and 6) possibility to select specific Treg phenotype before administration, compared with therapy with siRNA-transfected DCs. On the other hand, the advantages of therapy with siRNA-transfected DCs presented herein include: 1) less time for preparation in vitro, 2) less cost, and 3) possibilities of tolerance, anergy, and apoptosis by modified DCs,6,32 compared with therapy with siRNA-induced Tregs.

In this study, we report a novel antigen-specific therapy for the control of allergic diseases, using Tregs induced by CD40-silenced antigen-specific DCs transfected with CD40 siRNA in vitro, and siRNA-induced antigen-non-specific Tregs for the prevention of allergic diseases. Furthermore, antigen-specific Tregs induced by siRNA-modulated DCs are attractive since they have more potent inhibiting effects on allergic responses and symptoms than antigen non-specific Tregs.

Financial disclosure
This study is partially supported by Grants-in-Aid for Scientific Research C (15K10789) from Japan Society for the Promotion of Science.

Conflict of interest
None

Authors’ contributions
Motohiko Suzuki and Yoshihisa Nakamura designed the study. Motohiko Suzuki and Makoto Yokota wrote the manuscript. Makoto Yokota and Shinya Ozaki contributed to data collection. Shinya Ozaki and Yoshihisa Nakamura performed the statistical analysis and interpretation of the results. All authors read and approved the final manuscript.

Tregs to treat allergic diseases

NEW author guidelines for APJAI (effective as of February 1, 2017)

Please submit your manuscript via on-line submission system at the following address: http://www.apjai-journal.org.

Mission Statement

The Asian Pacific Journal of Allergy and Immunology (APJAI) publishes original research articles, clinical observations, case reports and reviews on various aspects of allergy and immunology provided that they have not been, and will not be, published elsewhere in whole, or in part, without the Editor’s permission. Papers accepted become the copyright of the Journal. Authors are responsible for all statements in articles submitted to the APJAI.

Journal Publication Policies and Procedures

The APJAI will consider for publication those papers directly related to allergy and immunology and has agreed to follow the Uniform Requirements for Manuscripts Submitted to Biomedical Journals (the “Uniform Requirements”) of the International Committee of Medical Journal Editors (ICMJE), the full text of which is available at http://www.icmje.org. The manuscript submission instructions for the APJAI submission are consistent with the 2009 version of the Uniform Requirements. The Editor assumes that upon submission of a manuscript, all listed authors have agreed with the APJAI policies. Manuscripts that do not meet these guidelines will be returned to the submitting author for revision prior to any further consideration for peer review.

Submissions will be considered for publication in APJAI only if they are submitted solely to APJAI. It must not have been previously published and must not be under consideration for publication elsewhere. All published manuscripts become the permanent property of the APJAI and may not be published elsewhere without written permission.

Ethical Approval of Studies and Informed Consent

For all research studies involving human subjects or research material derived from humans, a statement describing approval by the appropriate Institutional Review Board (IRB) is required in the Methods Section. Authors must declare how and if the informed consents were obtained from the study participants, if the study is conducted in humans, in the Methods Section. Studies exempted from IRB approval by their respective boards should be indicated in the Methods Section. Institutional Review Board approval and informed consent statements are not required for Case Reports. Studies involving experimental animals must include a statement in the Methods Section indicating that institutional or national guidelines were followed for the care and use of the animals. Failure to comply with this requirement will result in the manuscript being returned without review.

Clinical Trial Registration

APJAI requires investigators to preregister their clinical trials in a public trials registry approved by WHO (http://www.who.int/ictrp/network/primary/en/).

APJAI has adopted the WHO’s definition of a clinical trial: “any research study that prospectively assigns human participants or groups of humans to one or more health-related interventions to evaluate the effects on health outcomes.” The clinical trial registration number and name of the registry should be clearly identified on the title page and in the Methods Section.

Manuscript Preparation and Submission Requirements (NEW!!)
The authors must submit the cover letter, title page, abstract, manuscript text, tables, figures, and/or supplement files. Please read the instruction in the online submission system carefully as many changes have been implemented. All manuscripts are subjected to open peer-review. Before submitting a manuscript, please gather the following information:

- All Author
  - First and Last Names
  - Postal Addresses
  - Work Telephone Numbers (for Corresponding Author only)
  - E-mail addresses
- Title (you can copy and paste this from your manuscript)
- Abstract (you can copy and paste this from your manuscript)
- Manuscript files in Word (Please make sure the “Language” is “English (U.S.)” via Tools->Language->Set Language), WordPerfect, EPS, text, Postscript, PDF, or RTF format.
- Cover Letter, including job title and institution for EVERY Author listed on the manuscript.
- Figures/Images should be in TIFF, GIF, JPG, PDF, Postscript, or EPS format.

Submission Process

The four steps of the submission process are: Files, Manuscript Information, Validate, and Submit. The four steps each contain sub-steps that can be accessed by clicking on their respective tabs. Navigating through this “Tab View” will save any entered information each time a new tab is clicked (or the boxes "Save and Continue" and "Next" are clicked). Each step and sub-step is listed below:

1. Files
   - Upload Files
     A screen asking for the actual file locations (via an open file dialog) will appear. After completing this screen, your files will be sent to be converted to PDF for the peer review process.
   - Remove Files
     Allows the user to remove previously uploaded files.
   - Replace Files
     Allows the user to replace any previously submitted files with another file.
   - File Type
     This tab prompts the user to choose the “file type” that corresponds to the upload document. Though the file types can vary from journal to journal, the five basic types of files are, Author Cover Letter, Article File, Figure, Table, Supplemental Material.
4. Submit

This screen is the final step of the submission process. The system will check to make sure everything is completed before the manuscript is submitted. If the manuscript is ready for submission, then there will be text that reads: “Your manuscript is ready to be submitted. Click the link below to finalize your submission.” Otherwise, it will ask that you modify your submission to fulfill all of the submission requirements.

5. Submission Fee

A nonrefundable processing fee of USD $40 is due upon submission. No submission fee is required for invited review articles. If a fee is required, you will be asked to pay it online using credit card at the time of submission. Please note that purchase orders and bank wire transfers cannot be accepted for the processing fee. Manuscript will not be processed further unless the submission fee is received by APJAI editorial office.

6. Manuscript Format

Manuscripts should be type-written in English with font style Times New Roman, font size 12. All pages should be numbered consecutively at the top right-hand corner, beginning with the title page. The manuscript must display continuous line numbers (1, 2, 3, and so forth) in the left margin, beginning with the title page. (Line numbering can be added from the Page Setup or Format menu of word processing programs.) All sections of the manuscript should be typed, double-spaced with margins of at least one inch on all sides and arranged in the following order:

6.1 The title page MUST have the following information
- Title of the manuscript
- first and last names of the authors; no initials allowed unless it is a middle name
- authors and their perspective highest academic degree(s)
  example: Jane S Doe, MD, PhD , John K Watson, MSc , Katherine Gibson, BSc
- Authors’ affiliation(s)
- Short running title
- Name of the corresponding author
- Address of the corresponding author including telephone, fax number and email address
- Clinical trial registration number (if applicable)
- word count for abstract
- word count for text
- Indicate total number of references
- Indicate total number of tables and figures (no more than a total of 2 figures and tables combined).
  Example: 250 abstract; 3500 text; 35 references; 2 tables; 4 figures

6.2 Structured abstract with the following subheadings and not more than 250 words total (including the subheadings)

Abstract must be written in a structured format with the following headings: background; objective; methods; results; and conclusion. The major points of the article should be summarized in 150 (case reports) to 250 words (original research and review articles), in the order of their appearance in the manuscript. Abbreviations should be kept to an absolute minimum. References are not allowed in the abstract.

Keywords (at least 5 words or key phrases)

A minimum of 5 key words or brief phrases should be listed below the abstract for indexing purposes. The Medical Subject Headings (MeSH) used by the US National Library of Medicine's Index Medicus (MEDLINE) are preferred.

2. Manuscript Information

- Title, Abstract
  It is required for the user to provide a Title for manuscript as well as a Running Title and an Abstract. The Title, Running Title, and Abstract all have word or character limits. (See details in Manuscript Format)

- Authors
  This tab prompts the user to submit General Information about the author. The fields marked with an asterisk (*) are required, and need to be completed to continue the submission process.

- Keywords & Subject Areas
  A screen where the author provides at subject areas of the manuscript from the list provided. If needed, the author can provide keywords for the manuscript by typing it in any boxes that might be provided.

- Detailed Information
  This screen asks for more detailed information regarding the manuscript. Though the questions in this tab may vary from journal to journal, typical questions include “Conflict of Interest” and “Dual Publication”.

- Author Review Suggestions
  This screen allows the user to provide “suggested reviewers” to include for the revision process. The author can also provide reviewers to exclude from the revision process.

3. Validate

- Approve Files
  The screen allows the user to verify that the manuscript has been uploaded and converted to the PDF format correctly.

- Approve Manuscript
  This screen provides the user with all the information gathered from the submission process. It will provide a summary of all of the data entered so far, with the option to change any of those items.

- File Description
  When uploading a file type labeled “Figure”, “Table”, or “Supplemental Material” it is required to give a brief description of the content that is included in the file.

- File Order
  This tab allows the user to rearrange files to be displayed at the author’s discretion. This tab also gives the option to merge PDF files into a single PDF file to display to the Editor and Reviewers. Upon completion the user must check the checkbox indicating completion of the ordering and selection process.

- Manuscript Information
  - Title, Abstract
    It is required for the user to provide a Title for manuscript as well as a Running Title and an Abstract. The Title, Running Title, and Abstract all have word or character limits. (See details in Manuscript Format)

- Authors
  This tab prompts the user to submit General Information about the author. The fields marked with an asterisk (*) are required, and need to be completed to continue the submission process.

- Keywords & Subject Areas
  A screen where the author provides at subject areas of the manuscript from the list provided. If needed, the author can provide keywords for the manuscript by typing it in any boxes that might be provided.

- Detailed Information
  This screen asks for more detailed information regarding the manuscript. Though the questions in this tab may vary from journal to journal, typical questions include “Conflict of Interest” and “Dual Publication”.

- Author Review Suggestions
  This screen allows the user to provide “suggested reviewers” to include for the revision process. The author can also provide reviewers to exclude from the revision process.

- Approve Files
  The screen allows the user to verify that the manuscript has been uploaded and converted to the PDF format correctly.

- Approve Manuscript
  This screen provides the user with all the information gathered from the submission process. It will provide a summary of all of the data entered so far, with the option to change any of those items.

- Submit
  This screen is the final step of the submission process. The system will check to make sure everything is completed before the manuscript is submitted. If the manuscript is ready for submission, then there will be text that reads: “Your manuscript is ready to be submitted. Click the link below to finalize your submission.” Otherwise, it will ask that you modify your submission to fulfill all of the submission requirements.
6.3 Main text

This section must have the following headings: Introduction, Methods, Results, Discussion, and Conclusion. In the text, cite references sequentially in superscript arabic numerals, e.g., 1, 2, 3. Tables must be numbered sequentially in the text with Arabic numerals (1, 2, 3, 4, etc.). Figures must be numbered sequentially in the text with Arabic numerals (1, 2, 3, 4, etc).

Introduction

This section should state the specific purpose, research objective, or hypothesis of the study and should provide a context or background information for the study. The aims of the manuscript should be clearly stated. Papers most closely related to the issue of the study may be mentioned. The introduction should not contain either findings or conclusions.

Methods

This section should be concise but provide sufficient detail to allow the work to be repeated by others. The source of material should be given in detail, where possible. Describe the design, subjects, setting, interventions, and main outcome measures. The explanation of the experimental methods provides technical information, apparatus details, and procedures. Describe statistical methods with sufficient detail to enable a reader with access to the original data to verify the reported results. For all research studies including human subjects (excluding Case Reports) the specific IRB that has approved the research must be indicated. Additionally a statement that informed consent was obtained from all research participants must be included. The clinical trial registration number and place of registry should be informed for clinical trial studies.

Results

Describe the experimental data and results as well as the particular statistical significance of the data. Results should be presented in a logical sequence in the text, tables and figures. Excessive repetition of the same data in different forms should be avoided. The Consolidated Standards of Reporting Trials (CONSORT) statement is a set of guidelines for reporting on the methods and results of randomized and nonrandomized medical research studies and is available at the following Website: http://www.consort-statement.org.

Discussion

Provide and quantify the main outcomes of the study. The data should be interpreted concisely, without repeating data already presented in the results section. Identify limitations of the presented data including plausible explanations for discrepancies between the data and the literature, any differences not expected from the initial hypothesis presented in the introduction and a measured description of the conclusions of the study with implications for future research, biological understanding and/or clinical applications.

6.4 Acknowledgements

Conflict of interest (in the past 3 years)
Source of funding with grant numbers (if applicable)
Author contributions

6.5 References

not more than total of 35 for original research papers
not more than 70 for review papers
Vancouver style (you can download the APJAI endnotes style here (URL))

Examples

Books and other monographs

6.6 Figure legends

Figure legends should be typewritten, double -spaced, and listed on a separate page after the tables. They should not appear on the figures. List all of the figure titles in the figure legend. The legends should identify the data or subject being presented and its legend are understandable without reference to the text. Figures should be professionally drawn and photographed. Colored photographs may be published and additional expense will be paid by the authors. Titles and detailed explanations belong in the figure legends, not on the figures themselves. Photomicrographs must have internal scale markers. Symbols, arrows, or letters used in the photomicrographs should contrast with the background. If a figure has been published, acknowledge the original source and submit written permission from the copyright holder to reproduce the material.

6.7 Tables

Tables should be numbered in the order in which they are first cited in the text with Arabic numerals (1, 2, 3, 4, etc). They should be on separate pages, one table per page. Each table should have a concise heading that makes it comprehensible without reference to the text of the article. Use horizontal lines only at the top and bottom of the table and between column headings and the body of the table. Use no vertical lines. Explain any nonstandard abbreviations in the footnote of the table, e.g., Abbreviations: CT, computed tomography; MRI,
magnetic resonance imaging: OR, odds ratio. Footnotes in captions should appear at the bottom of the table.

Please use the program's page break function to begin each section on a new page.

6.8 Figure

Figures (graphs, charts, photographs, and illustrations) should be numbered in the order in which they are first cited in the text.

All figures must be numbered sequentially with Arabic numerals (1, 2, 3, 4, etc.). Graphics should be saved in CMYK (cyan, magenta, yellow, black) rather than RGB (red, green, blue). The resolution specification for TIFF and EPS files is 800 dpi for monochrome, figures that are black and white only and line shots; 250-300 dpi for gray/CMYK or color photographs, and 600 dpi for combinations, such as photographs labeled with letters or other markings. One figure per page.

Manuscripts should be written in proper and clear English so that they are understandable to any reader who is not a specialist in the field. Authors may be requested to have the English of the manuscript checked and improved by language editing services before submission. All measurements must be given in SI units as outlined in the latest edition of Units, Symbols and Abbreviations: A Guide for Medical and Scientific Editors and Authors (Royal Society of Medicine Press, London). However, liter and molar are permitted. Abbreviations should be used sparingly and only where they reduce repetition of long, technical terms. Initially use the word in full, followed by the abbreviation in parentheses. Thereafter use the abbreviation. All manuscripts must be submitted via online at the following address: http://www.apjai-journal.org/. Article Types

The APJAI publishes original articles, review articles, and case reports. Topics of interest include all subjects that relate to the basic and clinical aspects of allergy and immunology.

- **Original Research Articles:** The text of original articles should be divided into sections with the following headings in this order: Introduction, Methods, Results, Discussion, and Conclusion. The total text should not exceed 3,500 words (excluding the Abstract, References, and Figure/Table Legends). These should describe fully, but as concisely as possible, the results of original clinical and/or laboratory research. Original articles should have a structured abstract with the following headings: Background, Objective, Methods, Results and Conclusions (maximum 250 words). A minimum of 5 keywords for indexing, and no more than 35 references are required. Text should not exceed 3,500 words. Advice on appropriate sectioning of original articles can be found in the ICMJE’s Uniform Requirements. Each original article may be accompanied by a combination of no more than 6 figures and tables. Original article manuscripts that are determined to significantly exceed these limits may be returned to the authors for shortening prior to review. The manuscript should be organized in the following order: title page WITH the names of the authors and affiliations (please see title page requirement mentioned above); abstract and key words; main text; acknowledgements; references; figure legends; tables (each table complete with title and footnotes), and figures. Figures should look sharp and crisp when viewed at 100% magnification. Please note that should your manuscript be accepted, the journal may request for higher resolution TIFF or EPS files.

- **Review Articles:** Review articles are mostly invited by the Editors. Authors interested in submitting a review article should contact the Editor-in-Chief in advance to determine the appropriateness of any proposed review prior to submitting a full manuscript. Review articles address a specific question or issue that provide an evidence-based, review on a focused topic, either clinical or basic science. Review articles should have a structured abstract (250 words or less) with the following headings Objective, Data Sources, Study Selections, Results and Conclusion, a minimum of 5 keywords, and no more than 70 references. Text should not exceed 5,000 words and should be organized into the following sections: Introduction, Body, Discussion and Conclusions.

- **Case Reports:** Case Reports should have an unstructured abstract of no more than 150 words, a minimum of 5 keywords, a maximum of 2 tables or figures and 20 references. The main text should not exceed 1,500 words and should be organized into the following sections: Introduction, Report of Case and Discussion. A fully structured abstract is not necessary for a Case Report. For guidance on acceptable handling of photographs and other safeguards of patient confidentiality and anonymity, refer to section II.E.1 of the ICMJE’s Uniform Requirements: Patients and Study Participants.

- **Short Communications:** Short communications are short research articles intended to present exciting finding. Short communications are limited to 1000 words for the body of the text, 8 references and may include no more than 1 figure or 1 table. Manuscripts should be organized as described for original research article and abstract.

Privacy Statement

The names and email addresses entered in this journal site will be used exclusively for the stated purposes of this journal and will not be made available for any other purpose or to any other party. Authors must omit from their manuscripts any identifying details regarding patients and study participants, including patient names, initials, social security numbers, and hospital numbers. Patient details may be included only if they are essential for scientific purposes and the authors have obtained written informed consent from the patient, parent, or guardian for publication purposes.

Publication Fees

A sum of US $400.00 is charged to the corresponding author of each article published in the APJAI. A pdf file will be provided to the corresponding author. In case of English editing required by reviewers, US $80.00 is charged additionally. If the manuscript has been checked by a certified institute, please submit the certificate. Additional fee for reprints and color illustrations are charged to the authors separately.
Page Proofs

APJAI will provide the corresponding author with galley proofs for review/correction. Corresponding authors will receive a PDF file of the typeset pages to check the copyediting before publication. Authors should make only necessary changes and return the corrected page proofs to the Editor within 3 business days.

Transfer of Copyright

All manuscripts accepted for publication become the property of APJAI. All authors must read, agree to the conditions outlined in the Authorship Form and Copyright Transfer Form. These forms must be filled out and signed as eForm. Articles cannot be published until an eForm of Authorship and Copyright Transfer Form has been received. Published articles may not be published elsewhere, in English or any other language, without the permission of the Editor-in-Chief of APJAI.
